

Additional Temporal Logic Operators

Aligned with p1800-2008-draft 4

Objectives:

Currently SVA supports properties formed from sequences, suffix implications, property operators and, or, not, if-else, and recursion. Although recursion provides much expressive power, the verification community that has used assertions in the past is also accustomed to Linear Temporal Logic. Introducing such operators to SVA would provide a significant advantage by enabling flexible forms for expressing properties, and reducing the need for indirect property definitions created through negation. Such operators are also part of the PSL standard. SVA would have the advantage of combining the proposed operators with recursion and local variables.

Furthermore, the dual forms (so called *followed_by*) of the suffix implications are also included in the proposal, using the syntax `##` and `##=` for the overlapping and non-overlapping versions, respectively. These operators are particularly useful when creating coverage properties in which regular concatenation (`##`) cannot be used.

Some examples:

- SVA: `!g[*1:$] |-> f // weak until`
LTL: `f until g`

- SVA: `property prop_always(p); p and (1'b1 |=> prop_always(p)); endproperty`
LTL: `property prop_always(p); always p; endproperty;`

- SVA: `not (##[1:$] (e) |-> ##[1:$] !(e));`
LTL: `eventually always e;`

Another important application of the proposed operators is their ability to make property libraries more generic, since their plug-in capabilities are not restricted. As an example consider a property saying that some condition must hold between the start event and the end event. In the sequence-based implementation

```
property between(start_ev, end_ev, cond);
    start_ev ##0 !(end_ev && cond) [*1:$] |-> cond;
endproperty : between
```

`start_ev` may be any sequence, but the `end_ev` must be a boolean, since it is negated in the formula `!(end_ev && cond)`. In the implementation using the proposed operators no limitations are imposed on `end_ev`:

```
property between(start_ev, end_ev, cond);
    start_ev |-> cond until_with end_ev;
endproperty : between
```

(Note also that the new form is more intuitive than the original one.)

In addition to introducing the new operators in this proposal, the document also defines the concept of strong and weak sequences. It proposes to change the interpretation of sequence properties from the default "strong"

to "weak". The latter is the more usual interpretation in simulation and also the default in PSL. The keyword **strong** is introduced to this end and it can be applied to sequence expressions.

The existing definition in SVA is not intuitive: even innocently looking assertions turn out to be liveness. Consider the following example:

```
a1: assert property (@(posedge clk) a);
```

The assertion a1 is liveness, since it requires the clock to tick infinitely often. To make this assertion safety one should rewrite it as

```
a1: assert property (@(posedge clk) 1'b1 |-> not(!a));
```

which is awkward. It is likely that the existing tools simply ignore the liveness part of this assertion, but it is not compliant to the definition of the formal semantics in Annex F. Making a sequence property weak by default addresses this problem.

```

REPLACE

The result of property evaluation is either true or false. There are seven kinds of property: sequence, negation, disjunction, conjunction, if...else, implication, and instantiation.

- a) A property that is a sequence evaluates to true if, and only if, there is a nonempty match of the sequence. A sequence that admits an empty match is not allowed as a property. Because there is a match if, and only if, there is a first match, evaluation of such a property is the same as implicitly transforming its *sequence_expr* to *first_match(sequence_expr)*. As soon as a match of *sequence_expr* is determined, the evaluation of the property is considered to be true, and no other matches are required for that evaluation attempt.

- b) A property is a negation if it has the form **not** *property_expr*. For each evaluation attempt of the property, there is an evaluation attempt of *property_expr*. The keyword **not** states that the evaluation of the property returns the opposite of the evaluation of the underlying *property_expr*. Thus, if *property_expr* evaluates to true, then **not** *property_expr* evaluates to false; and if *property_expr* evaluates to false, then **not** *property_expr* evaluates to true.
- c) A property is a disjunction if it has the form
- ```
property_expr1 or property_expr2
```
- The property evaluates to true if, and only if, at least one of *property\_expr1* and *property\_expr2* evaluates to true.
- d) A property is a conjunction if it has the form
- ```
property_expr1 and property_expr2
```
- The property evaluates to true if, and only if, both *property_expr1* and *property_expr2* evaluate to true.
- e) A property is an **if-else** if it has either the form
- ```
if (expression_or_dist) property_expr1
```
- or the form
- ```
if (expression_or_dist) property_expr1 else property_expr2
```
- A property of the first form evaluates to true if, and only if, either *expression_or_dist* evaluates to false or *property_expr1* evaluates to true. A property of the second form evaluates to true if, and only if, either *expression_or_dist* evaluates to true and *property_expr1* evaluates to true or *expression_or_dist* evaluates to false and *property_expr2* evaluates to true.
- f) A property is an implication if it has either the form
- ```
sequence_expr l-> property_expr
```
- or the form
- ```
sequence_expr l=> property_expr
```
- The meaning of implications is discussed in [16.12.2](#).
- g) An instance of a named property can be used as a *property_expr* or *property_spec*. In general, the instance is legal provided the body *property_spec* of the named property can be substituted in place of the instance, with actual arguments substituted for formal arguments, and result in a legal *property_expr* or *property_spec*, ignoring local variable declarations. Thus, for example, if an instance of a named property is used as a *property_expr* operand for any property-building operator, then the named property must not have a **disable iff** clause. Similarly, clock events in a named property must conform to the rules of multiclock support when the property is instantiated in a *property_expr* or *property_spec* that also involves other clock events.

[Table 16-25](#) lists the sequence and property operators from highest to lowest precedence and shows the associativity of the non-unary operators.

Sequence operators	Property operators	Associativity
--------------------	--------------------	---------------

d) A property is a conjunction if it has the form

`property_expr1 and property_expr2`

The property evaluates to true if, and only if, both `property_expr1` and `property_expr2` evaluate to true.

e) A property is an if-else if it has either the form

`if (expression_or_dist) property_expr1`

or the form

`if (expression_or_dist) property_expr1 else property_expr2`

A property of the first form evaluates to true if, and only if, either `expression_or_dist` evaluates to false or `property_expr1` evaluates to true. A property of the second form evaluates to true if, and only if, either `expression_or_dist` evaluates to true and `property_expr1` evaluates to true or `expression_or_dist` evaluates to false and `property_expr2` evaluates to true.

f) A property is an implication if it has either the form

`sequence_expr1 -> property_expr`

or the form

`sequence_expr1 => property_expr`

The meaning of implications is discussed in 16.12.2.

g) An instance of a named property can be used as a `property_expr` or `property_spec`. In general, the instance is legal provided the body `property_spec` of the named property can be substituted in place of the instance, with actual arguments substituted for formal arguments, and result in a legal `property_expr` or `property_spec`, ignoring local variable declarations. Thus, for example, if an instance of a named property is used as a `property_expr` operand for any property building operator, then the named property must not have a `disable iff` clause. Similarly, clock events in a named property must conform to the rules of multiclock support when the property is instantiated in a `property_expr` or `property_spec` that also involves other clock events.

Table 16-25 lists the sequence and property operators from highest to lowest precedence and shows the associativity of the non-unary operators.

Sequence operators	Property operators	Associativity
<code>[*], [=], [->]</code>		—
<code>##</code>		Left
<code>throughout</code>		Right
<code>within</code>		Left
<code>intersect</code>		Left
	<code>strong, weak</code>	—
	<code>Not</code>	—
<code>and</code>	<code>And</code>	Left
<code>or</code>	<code>Or</code>	Left
	<code>if-else</code>	Right

	<code>accept_on, reject_on</code>	—
	<code>next, s_next</code>	—
	<code>always, s_always, eventually, s_eventually, until, s_until, until_with, s_until_with</code>	Left
	<code> ->, =></code>	Right
	<code>Implies</code>	Right
	<code>Iff</code>	Left

A `disable iff` clause can may be attached to a *property_expr* to yield a *property_spec*. `disable iff` (*expression_or_dist*) *property_expr* The expression of the `disable iff` is called the *reset expression*. The `disable iff` clause allows preemptive resets to be specified. For an evaluation of the *property_spec*, there is an evaluation of the underlying *property_expr*. If prior to the completion of that evaluation the reset expression becomes true, then the overall evaluation of the property results in disabled. A property has disabled evaluation if it was preempted due to a `disable iff` condition. A disabled evaluation of a property does not result in success or failure. Otherwise, the evaluation of the *property_spec* is the same as that of the *property_expr*. The reset expression is tested independently for different evaluation attempts of the *property_spec*. The values of variables used in the reset expression are those in the current simulation cycle, i.e., not sampled. The expression may contain a reference to an end point of a sequence by using the method *triggered* of that sequence. *Matched* and *ended* of a sequence and local variables cannot be used in the reset expression. If a sampled value function is used in the reset expression, the sampling clock must be explicitly specified in its actual argument list as described in 16.8.3. Nesting of `disable iff` clauses, explicitly or through property instantiations, is not allowed.

ADD before 16.12.1 Typed formal arguments in property declarations

16.12.1 Sequence property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

Sequence properties have three forms: *sequence_expr*, `weak`(*sequence_expr*) and `strong`(*sequence_expr*). `strong`(*sequence_expr*) evaluates to true if, and only if, there is a nonempty match of the sequence. `weak`(*sequence_expr*) evaluates to true if, and only if, there is no finite prefix that witnesses a non-match of the sequence. A sequence that admits an empty match is not allowed as a property.

Since only one match is needed, properties of the form *sequence_expr*, `(weak`(*sequence_expr*)), and `(strong`(*sequence_expr*)) are evaluated to *true* if and only if the properties `first_match`(*sequence_expr*), `(weak`(`first_match`(*sequence_expr*))) and `(strong`(`first_match`(*sequence_expr*))) are evaluated to *true* respectively. As soon as a match of *sequence_expr* is determined, the evaluation of the property is considered to be true, and no other matches are required for that evaluation attempt.

Without the `strong`, `weak` operators, the evaluation of *sequence_expr* depends on the verification statements in which it is being used. In case that the statement is `assert property` or `assume property`, it is evaluated as `weak`(*sequence_expr*), otherwise it is being evaluated as `strong`(*sequence_expr*).

The following examples illustrate the sequence property forms:

```
property p1;
    strong(##[0:$] a);
endproperty
property p2;
    weak(##[0:$] a);
```

```

endproperty
property p3;
    @(posedge clk) a;
endproperty

c1: cover property (p3);

a1: assert property (p3);

```

Property `p1` says that the sequence `##[0:$] a` shall match. This sequence matches if, and only if `a` eventually becomes true. Property `p2` is a tautology: it is true for any possible valuations of `a`. Indeed there is no evidence at any time that `##[0:$] a` has no match in the future. The cover property `c1` says that `clk` must rise at least once and that `a` is true when `clk` rises for the first time. The assertion `a1` says that if `clk` rises at least once, then `a` must be true when `clk` rises for the first time.

The not operator switch the strength of a property. In particular one should be careful when negating a sequence. For example consider the following assertion:

```
a1: assert property (not a ##1 b);
```

Since the sequential property `a ##1 b` is used in an assertion, it is weak. This means that at the last cycle of a simulation the sequential property `a ##1 b` always holds and thus, the assertion `a1` always fails. In this case it is more reasonable to use:

```
a2: assert property (not strong(a ##1 b));
```

16.12.2 Negation property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is a negation if it has the form `not property_expr`. For each evaluation attempt of the property, there is an evaluation attempt of `property_expr`. The keyword `not` states that the evaluation of the property returns the opposite of the evaluation of the underlying `property_expr`. Thus, if `property_expr` evaluates to true, then `not property_expr` evaluates to false; and if `property_expr` evaluates to false, then `not property_expr` evaluates to true.

16.12.3 Disjunction property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is a disjunction if it has the form

```
property_expr1 or property_expr2
```

The property evaluates to true if, and only if, at least one of `property_expr1` and `property_expr2` evaluates to true.

16.12.4 Conjunction property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is a conjunction if it has the form

```
property_expr1 and property_expr2
```

The property evaluates to true if, and only if, both `property_expr1` and `property_expr2` evaluate to true.

16.12.5 if-else property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is an **if-else** if it has either the form

```
if (expression_or_dist) property_expr1
```

or the form

```
if (expression_or_dist) property_expr1 else property_expr2
```

A property of the first form evaluates to true if, and only if, either `expression_or_dist` evaluates to false or `property_expr1` evaluates to true. A property of the second form evaluates to true if, and only if, either `expression_or_dist` evaluates to true and `property_expr1` evaluates to true or `expression_or_dist` evaluates to false and `property_expr2` evaluates to true.

Note to editor: Insert the subclause “Implication sub clause” here (as 16.12.6)

16.12.7 Implies and iff properties

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is an **implies** if it has the form `property_expr1 implies property_expr2`

A property of this form evaluates to true if and only if either `property_expr1` evaluates to false or `property_expr2` evaluates to true.

A property is an **iff** if it has the form `property_expr1 iff property_expr2`

A property of this form evaluates to true if and only if either `property_expr1` evaluates to false and `property_expr2` evaluates to false or `property_expr1` evaluates to true and `property_expr2` evaluates to true.

16.12.8 Property instantiation

Note to editor: Shift the numeration of the subsequent subclauses accordingly

An instance of a named property can be used as a *property_expr* or *property_spec*. In general, the instance is legal provided the body *property_spec* of the named property can be substituted in place of the instance, with actual arguments substituted for formal arguments, and result in a legal *property_expr* or *property_spec*. Thus, for example, if an instance of a named property is used as a *property_expr* operand for any property-building operator, then the named property must not have a **disable iff** clause. Similarly, clock events in a named property must conform to the rules of multiclock support when the property is instantiated in a *property_expr* or *property_spec* that also involves other clock events.

16.12.9 followed_by property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

The **followed_by** construct specifies that the checking of a property is required to proceed a match of a sequential antecedent

```
property_expr ::= //from A.2.10
...
| sequence_expr #-#property_expr
| sequence_expr ### property_expr
```

Syntax 16-15—Implication syntax (excerpt from Annex A)

This clause is used to precondition monitoring of a property expression and is allowed at the property level. The result of the followed_by is either true or false. The left-hand operand *sequence_expr* is called the *antecedent*, while the right-hand operand *property_expr* is called the *consequent*. The following points should be noted for #-# followed_by:

- From a given start point *sequence_expr* must have at least one successful match.
- *property_expr* shall be successfully evaluated starting from the end point of some successful match of *sequence_expr*.
- From a given start point, evaluation of the followed_by succeeds and returns true if, and only if, there exists a match of the antecedent *sequence_expr* beginning at the start point, and the evaluation of the consequent *property_expr* beginning at the end point of the match succeeds and returns true.

Two forms of followed_by are provided: overlapped using operator #-# and nonoverlapped using operator ###. For overlapped followed, there shall be a match for the antecedent *sequence_expr*, where at the end point of the match is the start point of the evaluation of the consequent *property_expr*. For nonoverlapped followed_by, the start point of the evaluation of the consequent *property_expr* is the clock tick after the end point of the match. Therefore, *sequence_expr* ### *property_expr* is equivalent to the following:

```
sequence_expr ### 1 #-# property_expr
```

The followed_by operators are the duals of the implication operators. Therefore, *sequence_expr* #-# *property_expr* is equivalent to the following:

```
not sequence_expr ### 1 |-> not property_expr
```

and *sequence_expr* ### *property_expr* is equivalent to the following:

```
not sequence_expr ### 1 |=> not property_expr
```

Examples:

```
property p1;
    ##[0:5] done #-# always !rst;
endproperty
property p2;
    ##[0:5] done ### always !rst;
endproperty
```

Property p1 says that *done* shall be asserted at some clock tick during the first 6 clock ticks, and starting from one of the clock ticks when *done* is asserted, *rst* shall always be low. Property p2 says that *done* shall be asserted at some clock tick during the first 6 clock ticks, and starting the clock tick after one of the clock ticks when *done* is asserted, *rst* shall always be low.

.Note that `sequence_expr ## strong(sequence_expr1)` is semantically equivalent to `strong(sequence_expr ##0 sequence_expr1)`, and `sequence_expr ==# strong(sequence_expr1)` is semantically equivalent to `strong(sequence_expr ##1 sequence_expr1)`.

The *followed_by* operators are especially convenient for specifying cover properties over sequences followed by a property.

16.12.10 Next property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is a **next** if it has one of the following forms:

- **next** `property_expr` (weak **next** operator)
- **next** [`constant_expression`] `property_expr` (iterated form of weak next)
- **s_next** `property_expr` (strong **next**)
- **s_next** [`constant_expression`] `property_expr` (iterated form of strong next)

Weak **next** property evaluates to true if `property_expr` holds at the next clock tick or if there are no further clock ticks. To require the clock tick to occur, use the strong form **s_next** `property_expr`. Weak next property with expression evaluates to true if `property_expr` holds in the specified of future clock ticks indicated by the constants, or if there are not enough clock ticks for the property to complete the evaluation. To require the necessary clock ticks to occur use the strong form **s_next** [`constant_expression`] `property_expr`.

Note that **next** `property_expr` is semantically equivalent to `1 |=> property_expr`, and that **s_next** `property_expr` is semantically equivalent to `1 ### property_expr`.

Examples.

```
property p1;
    next a;
endproperty
property p2;
    s_next a;
endproperty
property p3;
    next always a;
endproperty
property p4;
    s_next always a;
endproperty
property p5;
    next s_eventually a;
endproperty
property p6;
```

```

    s_next s_eventually a;
endproperty
property p7;
    next [2] a;
endproperty
property p8;
    s_next [2] a;
endproperty

```

The property `p1` says that if the property clock ticks once more, then `a` shall be true at the next clock tick. The property `p2` says that the property clock shall tick once more and `a` shall be true at the next clock tick. The property `p3` says that while its clock ticks, `a` shall be true at each future clock tick starting from the next clock tick. Property `p4` says that the property clock shall tick at least one more time and while it ticks, `a` shall be true at each future clock starting from the next clock tick. The property `p5` says that if the property clock ticks at least once, it shall tick enough times for `a` to be true at some point in the future starting from the next clock tick. The property `p6` says that should be true sometime in the strict future.

The properties `p7` and `p8` say that `a` shall be true the second clock ticks; `p7` does not require the clock to tick, while `p8` does. `p7` is equivalent to **weak** (`##2 a`), and `p8` is equivalent to **strong** (`##2 a`).

16.12.11 always property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is an **always** if it has one of the following forms:

- **always** `property_expr`
- **always** [`cycle_delay_const_range_expression`] `property_expr` (ranged form of `always`)
- **s_always** [`constant_range`] `property_expr` (ranged strong form of `s_always`)

Note that there is no strong form of **always** operator without range, and that there is no unbounded form of the strong form of **always**.

A property **always** `property_expr` evaluates to true if `property_expr` holds at every clock tick. A property **always** [`cycle_delay_const_range_expression`] `property_expr` evaluates to true if `property_expr` holds at every clock tick within the range of future clock ticks, or if there are not enough clock ticks for the property to complete the evaluation. To require the necessary clock ticks to occur use the strong form **s_always** [`constant_range`] `property_expr`.

There is also the implicit **always** that is associated with the verification statements (see 16.13.4). In that case the verification statement will evaluate the underlying `property_expr` starting at every occurrence of its leading clocking event, unless the verification statement is placed inside an **initial** block. The implicit **always** in the following example will succeed in every attempt, if and only if the explicit **always** will succeed in its single attempt:

Implicit form:

```
assert property (p);
```

Explicit form:

```
initial assert property (always p);
```

This is not shown as a practical example, but only for illustration of the meaning of **always**.

Examples.

```
initial a1: assume property( @(posedge clk) reset[*5] #-# always !reset;
property p1;
    a ##1 b |=> always c;
endproperty
property p2;
    always [2:5] a;
endproperty
property p3;
    s_always [2:5] a;
endproperty
property p4;
    always [2:$] a;
endproperty
property p5;
    s_always [2:$] a; // Illegal
endproperty
```

The assertion `a1` says that `reset` shall be 1 for the first 5 clock ticks and then remain 0 for the rest of the computation. The assertion is being evaluated once starting at the first clock tick. The property `p1` says that if there is `a` followed by `b` then starting from the next clock tick after `b` `c` shall be forever true. The properties `p2` and `p3` say that during the clock ticks 2, 3, 4, and 5 `a` shall be true. The difference between them is that `p3` requires the property clock to tick at least 5 more times. The property `p4` is true if `a` remains true starting from the second clock tick (the clock is not required to tick). The property `p5` is illegal since specifying an unbounded range is not permitted with the strong form of an **always** property.

16.12.12 until property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is an **until** if it has one of the following forms:

- `property_expr1 until property_expr2` (weak non-overlapping form)
- `property_expr1 until_with property_expr2` (weak overlapping form)
- `property_expr1 s_until property_expr2` (strong non-overlapping form)
- `property_expr1 s_until_with property_expr2` (strong overlapping form)

An **until** property of the non-overlapping form evaluates to true if `property_expr1` evaluates to true at every clock tick until at least one tick before a clock tick where `property_expr2` evaluates to true. The overlapping form evaluates to true if `property_expr1` evaluates to true at every clock tick until and including a clock tick at which `property_expr2` evaluates to true. The strong forms of an **until** property require that `property_expr2` eventually happens in the future (this also includes the requirement from the property clock to tick enough times), while the weak forms evaluate to true even if `property_expr2` never happens provided that `property_expr1` is always true at each clock tick.

Examples.

```
property p1;
    a until b;
endproperty
property p2;
    a s_until b;
endproperty
property p1;
    a until_with b;
endproperty
property p1;
    a s_until_with b;
endproperty
```

The property `p1` says that `a` remains true until (not including) `b` becomes true. If `b` never becomes true `a` shall remain true forever. The property `p1` is equivalent to `a[*0:$] ##1 b`. The property `p2` says that `a` remains true until (not including) `b` becomes true, and that `b` shall eventually happen. The property `p2` is equivalent to **strong**(`a[*0:$] ##1 b`). The property `p3` says that `a` remains true until (including) `b` becomes true. If `b` never becomes true `a` shall remain true forever. The property `p3` is equivalent to `a[*0:$] ##0 b`. The property `p4` says that `a` remains true until (including) `b` becomes true, and that `b` shall eventually happen. The property `p2` is equivalent to **strong**(`a[*0:$] ##0 b`).

16.12.13 eventually property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

A property is an **eventually** if it has one of the following forms form

```
s_eventually property_expr
eventually [constant_range] property_expr
                                     (ranged weak form of eventually)
s_eventually [cycle_delay_const_range_expression] property_expr
                                     (ranged strong form of eventually)
```

Note that there is no weak form of **eventually** operator without range, and that there is no unbounded form of the weak **eventually** operator.

The **s_eventually** property evaluates to true if `property_expr` evaluates to true in a finite number of clock ticks, and the clock shall tick enough times for `property_expr` to happen. Weak eventually property with range evaluates to true if `property_expr` holds somewhere within the range of future clock ticks indicated by the constants, or if there are not enough clock ticks for the property to complete the evaluation. To require the necessary clock ticks to occur use the strong form **s_eventually** [`constant_range`] `property_expr`. The `constant_range` may be unbounded for the strong form, but shall be bounded for the weak form.

Examples.

```
property p1;
    eventually a;
endproperty
```

```

property p2;
    eventually always a;
endproperty
property p3;
    always eventually a;
endproperty
property p4;
    eventually [2:5] a;
endproperty
property p5;
    s_eventually [2:5] a;
endproperty
property p6;
    eventually [2:$] a; // Illegal
endproperty
property p7;
    s_eventually [2:$] a;
endproperty

```

The property `p1` says that `a` shall happen some time in the future. It is equivalent to `##[*0:$] a`. The property `p2` says that starting from some point on `a` should be always true. The property `p3` says that for infinite computations `a` shall becomes true infinitely many times, and for finite words, `a` should hold at the last clock tick.

The properties `p4` and `p5` say that `a` shall be true at some tick between the second and the fifth clock ticks; `p4` does not require the clock to tick, while `p5` does. `P4` is equivalent to `weak(##[2:5] a)`, and `p5` is equivalent to `strong(##[2:5] a)`. The property `p6` is illegal since an unbounded range cannot be used with the weak `eventually` form. The property `p7` says that the clock shall tick enough times and `a` shall happen in the future,

16.12.14 `accept_on` and `reject_on` property

Note to editor: Shift the numeration of the subsequent subclauses accordingly

Insert description from Mantis 1757

16.12.15 Weak and strong operators

Note to editor: Shift the numeration of the subsequent subclauses accordingly

The property operators `s_next`, `s_always`, `s_eventually`, `s_until`, `s_until_with` and strong sequence are strong: they require that some terminating condition happen in the future, and this includes the requirement that the property clock tick enough time to enable the condition to happen. The property operators `next`, `always`, `until`, `eventually`, `until_with` and weak sequence are weak, they don't impose any requirement on the terminating condition, and don't require the clock to tick.

The concept of weak and strong operators is closely related to an important notion of safety properties. Safety properties have the characteristic that all their failures happen at a finite time. E.g., the property `always a` is safety since it is violated only if at some (finite) time `a` becomes false. To the contrary, a failure of the

property `s_eventually a` cannot be identified in a finite time: if it is violated, the value of `a` must be always false.

16.12.16 Recursive properties

Note to editor: Shift the numeration accordingly

REPLACE

- RESTRICTION 1: The negation operator **not** cannot be applied to any property expression that instantiates a recursive property. In particular, the negation of a recursive property cannot be asserted or used in defining another property.

WITH

- RESTRICTION 1: The negation operator **not** and strong operators **s_next**, **s_eventually**, **s_always**, **s_until**, and **s_until_with** cannot be applied to any property expression that instantiates a recursive property. In particular, the negation of a recursive property cannot be asserted or used in defining another property.
