Section 29
SystemVerilog Data Read API

This chapter extends the SystemVerilog VPI with read facilities so that the Verilog Procedural Interface (VPI) acts as an Application Programming Interface (API) for data access and tool interaction irrespective of whether the data is in memory or a persistent form such as a file, and also irrespective of the tool the user is interacting with.

29.1 Motivation

SystemVerilog is both a design and verification language consequently its VPI has a wealth of design and verification data access mechanisms. This makes the VPI an ideal vehicle for tool integration in order to replace arcane, inefficient, and error-prone file-based data exchanges with a new mechanism for tool to tool, and user to tool interface. Moreover, a single access API eases the interoperability investments for vendors and users alike. Reducing interoperability barriers allows vendors to focus on tool implementation. Users, on the other hand, will be able to create integrated design flows from a multitude of best-in-class offerings spanning the realms of design and verification such as simulators, debuggers, formal, coverage or test bench tools.

29.1.1 Requirements

SystemVerilog adds several design and verification constructs including:

- C data types such as `int`, `struct`, `union`, and `enum`.
- Advanced built-in data types such as `string`.
- User defined data types.
- Test bench data types and facilities.

The access API shall be implemented by all tools as a minimal set for a standard means for user-tool or tool-tool interaction that involves SystemVerilog object data querying (reading). In other words, there is no need for a simulator to be running for this API to be in effect; it is a set of API routines that can be used for any interaction for example between a user and a waveform tool to read the data stored in its file database. This usage flow is shown in the figure below.

![Data read VPI usage model](image)

Our focus in the API is the user view of access. While the API does provide varied facilities to give the user the ability to effectively architect his or her application, it does not address the tool level efficiency concerns such as time-based incremental load of the data, and/or predicting or learning the user access. It is left up to implementors to make this as easy and seamless as possible on the user. To make this easy on tools, the API provides an initialization routine where the user specifies access type and design scope. The user should be pri-
marily concerned with the API specified here, and efficiency issues are dealt with behind the scenes.

### 29.1.2 Naming conventions

All elements added by this interface shall conform to the VPI interface naming conventions.

- All names are prefixed by vpi.
- All type names shall start with vpi, followed by initially capitalized words with no separators, e.g., vpiName.
- All callback names shall start with cb, followed by initially capitalized words with no separators, e.g., cbValueChange.
- All routine names shall start with vpi_, followed by all lowercase words separated by underscores (_), e.g., vpi_handle().

### 29.2 Extensions to VPI enumerations

These extensions shall be appended to the contents of the vpi_user.h file, described in IEEE Std. 1364-2001, Annex G. The numbers in the range 800 - 899 are reserved for the read data access portion of the VPI.

#### 29.2.1 Object types

All objects in VPI have a vpiType. This API adds a new object type for data traversal, and two other object types for object collection and traverse object collection.

```c
#define vpiTrvsObj 800 /* use in vpi_handle() */
#define vpiCollection 801 /* Collection of VPI handles */
#define vpiObjCollection 802 /* Collection of traversable design objs */
#define vpiTrvsCollection 803 /* Collection of vpiTrvsObj's */
```

The other object types that this API references, for example to get a value at a specific time, are all the valid types in the VPI that can be used as arguments in the VPI routines for logic and strength value processing such as `vpi_get_value(<object_handle>, <value_pointer>)`. These types include:

- Constants
- Nets and net arrays
- Regs and reg arrays
- Variables
- Memory
- Parameters
- Primitives
- Assertions

In other words, any limitation in vpiType of vpi_get_value() will also be reflected in this data access API.

#### 29.2.2 Object properties

This section lists the object property VPI calls.
29.2.2.1 Static info

/* Check */
#define vpiIsLoaded 804 /* use in vpi_get() */
#define vpiHasVC 805 /* use in vpi_get() */
#define vpiHasNoValue 806 /* use in vpi_get() */
#define vpiInExtension 807 /* use in vpi_get() */

/* Access */
#define vpiAccessLimitedInteractive 808 /* interactive */
#define vpiAccessInteractive 809 /* interactive: history */
#define vpiAccessPostProcess 810 /* data file */

/* Member of a collection */
#define vpiMember 811 /* use in vpi_iterate() */

/* Iteration on instances for loaded */
#define vpiDataLoaded 812 /* use in vpi_iterate() */

29.2.2.2 Dynamic info

29.2.2.2.1 Control constants

/* Control Traverse: use in vpi_control() or vpi_goto() */
for a vpiTrvsObj type */
#define vpiMinTime 813 /* min time */
#define vpiMaxTime 814 /* max time */
#define vpiPrevVC 815
#define vpiNextVC 816
#define vpiTime 817 /* time jump */

These properties can also be used in vpi_trvs_get_time() to enhance the access efficiency. The routine vpi_trvs_get_time() is similar to vpi_get_time() with the additional ability to get the min, max, current, previous VC, and next VC times of the traverse handle; not just the current place it points (as is the case for vpi_get_time()). These same vpiTypes can then be used for access or for moving the traverse handle where the context (get or go to) can distinguish the intent.

29.2.3 System callbacks

The access API adds no new system callbacks. The reader routines (methods) can be called whenever the user application has control and wishes to access data.

29.3 VPI object type additions

29.3.1 Traverse object

To access the value changes of an object over time, the notion of a Value Change (VC) traverse handle is added. A value change traverse object is used to traverse and access value changes not just for the current value (as calling vpi_get_time() or vpi_get_value() on the object would) but for any point in time: past, present, or future. To create a value change traverse handle the routine vpi_handle() is called with a vpiTrvsObj vpiType:

```c
vpiHandle object_handle; /* design object */
vpiHandle trvsHndl = vpi_handle(vpiType*/vpiTrvsObj,
/ */vpiHandle*/ object_handle);
```

A traverse object exists from the time it is created until its handle is released. It is the application’s responsibl-
ity to keep a handle to the created traverse object, and to release it when it is no longer needed.

### 29.3.2 VPI Collection

In order to read data efficiently, we may need to specify a group of objects for example when loading (or traversing) data we may wish to specify a list of objects that we want to mark as targets of data load (or traversal). To do this grouping we need the notion of a *collection*. A collection represents a user-defined collection of VPI handles. The collection is an ordered list of VPI handles. The vpiType of a collection handle can be vpiCollection, vpiObjCollection, or vpiTrvsCollection:

- A collection of type vpiCollection is a general collection of VPI handles of objects of any type.
- The collection object of type vpiObjCollection represents a collection of VPI *traversable* objects in the design.
- A vpiTrvsCollection is a collection of traverse objects of type vpiTrvsObj.

Our usage here in the read API is of either:

- Collections of traversable design objects: Used for example in vpi_read_load() to load data for all the objects. A collection of traversable design objects is of type vpiObjCollection (the elements can be any object type in the design except traverse objects of type vpiTrvsObj).
- Collections of data traverse objects: Used for example in vpi_control() (or vpi_goto()) to move the traverse handles of all the objects in the collection (all are of type vpiTrvsObj). A collection of traverse objects is a vpiTrvsCollection.

The collection contains a set of member VPI objects and can take on an arbitrary size. The collection may be created at any time and existing objects can be added to it. The purpose of a collection is to group design objects and permit operating on each element with a single operation applied to the whole collection group.

`vpi_iterate(vpiMember, <collection_handle>)` is used to create a member iterator. `vpi_scan()` can then be used to scan the iterator for the elements of the collection.

A collection object is created with `vpi_create()`. The first call gives NULL handles to the collection object and the object to be added. Following calls, which can be performed at any time, provide the collection handle and a handle to the object for addition. The return argument is a handle to the collection object.

For example:

```vpi
vpiHandle designCollection;
vpiHandle designObj;
vpiHandle trvsCollection;
vpiHandle trvsObj;
/* Create a collection of design objects */
designCollection = vpi_create(vpiObjCollection, NULL, NULL);
/* Add design object designObj into it */
designCollection = vpi_create(vpiObjCollection, designCollection, designObj);

/* Create a collection of traverse objects*/
trvsCollection = vpi_create(vpiTrvsCollection, NULL, NULL);
/* Add traverse object trvsObj into it */
trvsCollection = vpi_create(vpiTrvsCollection, trvsCollection, trvsObj);
```

Sometimes it is necessary to filter a collection and extract a set of handles which meet, or do not meet, a specific criterion for a given collection. The function `vpi_filter()` can be used for this purpose in the form of:

```vpi
vpiHandle colFilterHdl = vpi_filter((vpiHandle) colHdl, (PLI_INT32) filterType, (PLI_INT32) flag);
```

The first argument of `vpi_filter()`, *colHdl*, shall be the collection on which to apply the filter operation.
The second argument, `filterType` can be any `vpiType` or VPI Boolean property. This argument is the criterion used for filtering the collection members. The third argument, `flag`, is a Boolean value. If set to `TRUE`, `vpi_filter()` shall return a collection of handles which match the criterion indicated by `filterType`, if set to `FALSE`, `vpi_filter()` shall return a collection of handles which do not match the criterion indicated by `filterType`. The original collection passed as a first argument remains unchanged.

A collection object exists from the time it is created until its handle is released. It is the application’s responsibility to keep a handle to the created collection, and to release it when it is no longer needed.

**29.3.2.1 Operations on collections**

We define a method for loading data of objects in a collection: `vpi_read_load()`. This operation loads all the objects in the collection. It is equivalent to performing a `vpi_read_load()` on every single handle of the object elements in the collection.

A traverse collection can be obtained (i.e. created) from a design collection using `vpi_handle()`. The call would take on the form of:

```c
vpiHandle loadCollection;
/* Obtain a traverse collection from the load collection */
vpi_handle(vpiTrvsCollection, loadCollection);
```

The usage of this capability is discussed in Section 29.7.7.

We also define methods on collections of traverse handles i.e. collections of type `vpiTrvsCollection`. These methods are `vpi_control()` and `vpi_goto()`. Their function is equivalent to applying `vpi_control()` with the same time control arguments to move the traverse handle of every single object in the collection.

**29.4 Object model diagrams**

A traverse object of type `vpiTrvsObj` is related to its parent object; it is a means to access the value data of said object. An object can have several traverse objects each pointing and moving in a different way along the value data horizon. This is shown graphically in the model diagram below. The `traversable` class is a representational grouping consisting of any object that:

- Has a name
- Can take on a value accessible with `vpi_get_value()`, the value must be variable over time (i.e. necessitates creation of a traverse object to access the value over time).

The class includes nets, net arrays, regs, reg arrays, variables, memory, primitive, primitive arrays, concurrent
assertions, and parameters. It also includes part selects of all the design object types that can have part selects.

A collection object of type vpiObjCollection groups together a set of design objects Obj (of any type). A traverse collection object of type vpiTrvsCollection groups together a set of traverse objects trvsObj of type vpiTrvsObj.

**Figure 29-2 — Model diagram of traverse object**
29.5 Usage extensions to VPI routines

Several VPI routines have been extended in usage with the addition of new object types and/or properties. While the extensions are fairly obvious, they are emphasized here again to turn the reader’s attention to the extended usage.
## Table 29-1: Usage extensions to existing VPI routines

<table>
<thead>
<tr>
<th>To</th>
<th>Use</th>
<th>New Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Create an iterator for the loaded objects (using vpi_iterate(vpiData-Loaded, &lt;instance&gt;)). Create an iterator for (load or traverse) collections using vpi_iterate(vpiMember, &lt;collection&gt;).</td>
<td>vpi_iterate()</td>
<td>Add iteration types vpiData-Loaded and vpiMember. Extended with collection handle to create a collection member element iterator.</td>
</tr>
<tr>
<td>Obtain a traverse (collection) handle from an object (collection) handle</td>
<td>vpi_handle()</td>
<td>Add new types vpiTrvsObj and vpiTrvsCollection. Extended with collection handle (of traversable objects) to create a traverse collection from an object collection.</td>
</tr>
<tr>
<td>Obtain a property</td>
<td>vpi_get()</td>
<td>Extended with the new check properties: vpiIsLoaded, vpiHasVC, vpiHasNoValue, and vpiIsExtension</td>
</tr>
<tr>
<td>Get a value</td>
<td>vpi_get_value()</td>
<td>Use traverse handle as argument to get value where handle points</td>
</tr>
<tr>
<td>Get time traverse handle points at</td>
<td>vpi_get_time()</td>
<td>Use traverse handle as argument to get time where handle points</td>

</tr>
<tr>
<td>Filter a collection and extract a set of handles which meet, or do not meet, a specific criterion for a given collection</td>
<td>vpi_filter()</td>
</tr>
</tbody>
</table>

29.7 Reading data

Reading data is performed in 3 steps:

1) A design object must be selected for loading from a database (or from memory) into active memory.

2) Once an object is selected, it can then be loaded into memory. This step creates the traverse object handle used to traverse the design objects stored data.

3) At this point the object is available for reading. A traverse object must be created to permit the data value traversal and access.

29.7.1 VPI read initialization and load access initialization

Selecting an object is done in 3 steps:
1) The first step is to initialize the read access with a call to `vpi_load_extension()` to load the reader extension and set:

   a) Name of the reader library to be used specified as a character string. A NULL entry means that the default library (i.e. tool (e.g. simulator) the application is running under) is used. More details are in Section 29.9.

   b) Database file with stored data in case of `vpiAccessPostProcess` mode (see access mode).

   c) Access mode: The following VPI properties set the mode of access

      — `vpiAccessLimitedInteractive`: Means that the access will be done for the data stored in the tool memory (e.g. simulator), the history (or future) that the tool stores is implementation dependent. If the tool does not store the requested info then the querying routines shall return a fail. The file argument to `vpi_load_extension()` in this mode will be ignored (even if not NULL).

      — `vpiAccessInteractive`: Means that the access will be done interactively. The tool will then use the data file specified as a “flush” file for its data. This mode is very similar to the `vpiAccessLimitedInteractive` with the additional requirement that all the past history (before current time) shall be stored (for the specified scope/collection, see the access scope/collection description of `vpi_load_init()` (`vpi_load_init_create()`) later).

      — `vpiAccessPostProcess`: Means that the access will be done through the specified file. All data queries shall return the data stored in the specified file. Data history depends on what is stored in the file, and can be nothing (i.e. no data).

`vpi_load_extension()` can be called multiple times for different reader interface libraries (coming from different tools), database specification, and/or read access. A call with `vpiAccessInteractive` means that the user is querying the data stored inside the simulator database and uses the VPI routines supported by the simulator. A call with `vpiAccessPostProcess` means that the user is accessing the data stored in the database file and uses the VPI services provided by the waveform tool. The application, if accessing several databases and/or using multiple read API libraries, can use the routine `vpi_get(vpiInExtension, <vpiHandle>)` to check whether a handle belongs to that database. The call is performed as follows:

   ```c
   reader_extension_ptr->vpi_get(vpiInExtension, <vpiHandle>);
   ```

   where `reader_extension_ptr` is the reader library pointer returned after the call to `vpi_load_extension()`. TRUE is returned if the passed handle belongs to that extension, and FALSE otherwise. If the application uses the default library (i.e. the one provided by the tool it is running under), there is no need to use indirection to call the VPI routines; they can be called directly. An initial call must however be made to set the access mode, specify the database file, and check for error indicated by a NULL return.

   In case of `vpiAccessPostProcess` mode `vpi_read_close()` shall be called to close the opened database file. Handles obtained from the particular database that gets closed are no longer valid after this call.

   Multiple databases, possibly in different access modes (for example a simulator database opened in `vpiAccessInteractive` and a file database opened in `vpiAccessPostProcess`, or two different file databases opened in `vpiAccessPostProcess`) can be accessed at the same time. Section 29.9 shows an example of how to access multiple databases from multiple read interfaces simultaneously.

2) Next step is to specify the elements that will be accessed. This is accomplished by calling `vpi_load_init()` (or `vpi_load_init_create()`) and specifying a scope and/or an item collection. At least one of the two needs to be specified. If both are specified then the union of all the object elements forms the entire set of objects the user may access.

   — Access scope: The specified scope handle, and nesting mode govern the scope that access returns. Data queries outside this scope (and its sub-scopes as governed by the nesting mode) shall return a fail in the access routines unless the object belongs to `access collection` described below. It can be used either in a
complementary or in an exclusive fashion to access collection. NULL is to be passed to the collection when access scope is used in an exclusive fashion.

— Access collection: The specified collection stores the traverse object handles to be loaded. It can be used either in a complementary or in an exclusive fashion to access scope. NULL is to be passed to the scope when access collection is used in an exclusive fashion.

vpi_load_init() can be called multiple times. The load access specification of a call remains valid until the next call is executed. This routine serves to initialize the tool load access and provides an entry point for the tool to perform data access optimizations.

vpi_load_init_create() can be called anywhere vpi_load_init() is called. The two have the same function. In addition to initialization, vpi_load_init_create() creates a load collection list consisting of all the (valued) objects in the specified access scope if any (and its sub-scopes as governed by nesting mode) and the objects in the access collection if any. The return of vpi_load_init_create() is a collection handle, with NULL indicating failure.

29.7.2 Object selection for loading

In order to select an object for loading, we must first obtain the object handle. This can be done using the VPI routines (that are supported in the tool being used) for traversing the HDL hierarchy and obtaining an object handle based on the type of object relationship to the starting handle.

Any tool that implements this read API (e.g. waveform tool) shall implement at least a basic subset of the design navigation VPI routines that shall include vpi_handle_by_name() to permit the user to get a vpiHandle from an object name. It is left up to tool implementation to support additional design navigation relationships. Therefore, if the application wishes to access similar elements from one database to another, it shall use the name of the object, and then call vpi_handle_by_name(), to get the object handle from the relevant database. This level of indirection is always safe to do when switching the database query context, and shall be guaranteed to work.

It should be noted that an object’s vpiHandle depends on the access mode specified in vpi_load_extension() and the database accessed (identified by the returned extension pointer, see Section 29.9). A handle obtained through a post process access mode (vpiAccessPostProcess) from a waveform tool for example is not interchangeable in general with a handle obtained through interactive access mode (vpiAccessLimitedInteractive or vpiAccessInteractive) from a simulator. Also handles obtained through post process access mode of different file databases are not interchangeable. This is because objects, their data, and relationships in a stored file database could be quite different from those in the simulation model, and those in other file databases.

29.7.3 Loading objects

Once the object handle is obtained then we can use the VPI data load routine vpi_read_load() with the object’s vpiHandle to load the data for the specific object onto memory. Alternatively, for efficiency considerations, vpi_read_load() can be called with a design object collection handle of type vpiObjCollection. The collection must have already been created by either using vpi_create() (or vpi_load_init_create()) and the (additional) selected object handles added to the load collection using vpi_create() with the created collection list passed as argument. The object(s) data is not accessible as of yet to the user’s read queries; a traverse handle must still be created. This is presented in Section 29.7.4.

Note that loading the object means loading the object from a file into memory, or marking it for active use if it is already in the memory hierarchy. Object loading is the portion that tool implementors need to look at for efficiency considerations. Reading the data of an object, if loaded in memory, is a simple consequence of the load. The API does not specify here any memory hierarchy or caching strategy that governs the access (load or read) speed. It is left up to tool implementation to choose the appropriate scheme. It is recommended that this happens in a fashion invisible to the user. The API does provide the tool with the chance to prepare itself for data load and access with the vpi_load_init() (or vpi_load_init_create()). With this call, the tool can examine what objects the user wishes to access before the actual load and then read access is made.
29.7.3.1 Iterating the design for the loaded objects

The user shall be allowed to iterate for the loaded objects in a specific instantiation scope using \texttt{vpi\_iterate()}. This shall be accomplished by calling \texttt{vpi\_iterate()} with the appropriate reference handle, and using the property \texttt{vpiDataLoaded}. This is shown below.

a) Iterate all data read loaded objects in the design: use a NULL reference handle (\texttt{ref\_h}) to \texttt{vpi\_iterate()}, e.g.,

\begin{verbatim}
itr = vpi_iterate(vpiDataLoaded, /* ref\_h */ NULL);
while (loadedObj = vpi_scan(itr)) {
    /* process loadedObj */
}
\end{verbatim}

b) Iterate all data read loaded objects in an instance: pass the appropriate instance handle as a reference handle to \texttt{vpi\_iterate()}, e.g.,

\begin{verbatim}
itr = vpi_iterate(vpiDataLoaded, /* ref\_h */ instanceHandle);
while (loadedObj = vpi_scan(itr)) {
    /* process loadedObj */
}
\end{verbatim}

29.7.3.2 Iterating the load collection for its member loaded objects

The user shall be allowed to iterate for the loaded objects in the load collection using \texttt{vpi\_iterate()} and \texttt{vpi\_scan()}. This shall be accomplished by creating an iterator for the members of the collection and then use \texttt{vpi\_scan()} on the iterator handle e.g.

\begin{verbatim}
vpiHandle var\_handle; /* some object */
vpiHandle varCollection; /* object collection */
vpiHandle loadedVar; /* Loaded object handle */
vpiHandle itr; /* iterator handle */
/* Create load object collection */
varCollection = vpi_create(vpiObjCollection, NULL, NULL);
/* Add elements to the object collection */
varCollection = vpi_create(vpiObjCollection, var\_handle, var\_handle);

/* Iterating a collection for its elements */
itr = vpi_iterate(vpiMember, varCollection); /* create iterator */
while (loadedVar = vpi\_scan(itr)) {
    /* scan iterator */
    /* process loadedVar */
}
\end{verbatim}

29.7.4 Reading an object

So far we have outlined:

— How to select an object for loading, in other words, marking this object as a target for access.
— How to load an object into memory by obtaining a handle and then either loading objects individually or as a group using the load collection.
— How to iterate the design scope and the load collection to find the loaded objects if needed.

Reading an object means obtaining its value changes. VPI, before this extension, had allowed a user to query a value at a specific point in time--namely the current time, and its access does not require the extra step of load-
ing the object data. We add that step here because we extend VPI with a temporal access component: The user can ask about all the values in time (regardless of whether that value is available to a particular tool, or found in memory or a file, the mechanism is provided). Since accessing this value horizon involves a larger memory expense, and possibly a considerable access time, we have added also in this Chapter the notion of loading an objects’s data for read. Let’s see now how to access and traverse this value timeline of an object.

To access the value changes of an object over time we use a traverse object as introduced earlier in Section 29.3.1. Several VPI routines are also added to traverse the value changes (using this new handle) back and forth. This mechanism is very different from the “iteration” notion of VPI that returns objects related to a given object, the traversal here can walk or jump back and forth on the value change timeline of an object. To create a value change traverse handle the routine \texttt{vpiHandle()} must be called in the following manner:

\begin{verbatim}
vpiHandle trvsHndl = vpi_handle(vpiTrvsObj, object_handle);
\end{verbatim}

Note that the user (or tool) application can create more than one value change traverse handle for the same object, thus providing different views of the value changes. Each value change traverse handle shall have a means to have an internal index, which is used to point to its “current” time and value change of the place it points. In fact, the value change traversal can be done by increasing or decreasing this internal index. What this index is, and how its function is performed is left up to tools’ implementation; we only use it as a concept for explanation here.

Once created the traverse handle can point anywhere along the timeline; its initial location is left for tool implementation, however, if the traverse object has no value changes the handle shall point to the minimum time (of the trace), so that calls to \texttt{vpi_get_time()} can return a valid time. It is up to the user to call an initial \texttt{vpi_control()} to the desired initial pointing location.

\textbf{29.7.4.1 Traversing value changes of objects}

After getting a traverse \texttt{vpiHandle}, the application can do a forward or backward walk or jump traversal by using \texttt{vpi_control()} on a \texttt{vpiTrvsObj} object type with the new traverse properties.

Here is a sample code segment for the complete process from handle creation to traversal.

\begin{verbatim}
p_vpi_extension reader_p; /* Pointer to VPI reader extension structure */
vpiHandle instanceHandle; /* Some scope object is inside */
vpiHandle var_handle; /* Object handle */
vpiHandle vc_trvs_hdl; /* Traverse handle */
vpiHandle itr;
p_vpi_value value_p; /* Value storage */
p_vpi_time time_p; /* Time storage */
...
/* Initialize the read interface: Access data from memory */
/* NOTE: Use default VPI (e.g. that of simulator application is running */
under */
reader_p = vpi_load_extension(NULL, NULL, vpiAccessLimitedInteractive);
if (reader_p == NULL) ...; /* Not successful */

/* Initialize the load: Access data from simulator) memory, for scope */
instanceHandle and its subscopes */
/* NOTE: Call marks access for all the objects in the scope */
vpi_load_init(NULL, instanceHandle, 0);
itr = vpi_iterate(vpiVariables, instanceHandle);
while (var_handle = vpi_scan(itr)) {
    if (vpi_get(vpiIsLoaded, var_handle) == 0) { /* not loaded*/
        /* Load data: object-based load, one by one */
        if (!vpi_read_load(var_handle)); /* Data not found! */
    break;
    }
\end{verbatim}
/* Create a traverse handle for read queries */
vc_trvs_hdl = vpi_handle(vpiTrvsObj, var_handle);
/* Go to minimum time */
vpi_control(vpiMinTime, vc_trvs_hdl);
/* Get info at the min time */
vpi_get_time(vc_trvs_hdl, time_p); /* Minimum time */
vpi_printf(...);
vpi_get_value(vc_trvs_hdl, value_p); /* Value */
vpi_printf(...);
if (vpi_get(vpiHasVC, vc_trvs_hdl)) { /* Have VCs? */
  for (;;) { /* All the elements in time */
    if (vpi_control(vpiNextVC, vc_trvs_hdl) == 0) {
      /* failure (e.g. already at MaxTime or no more VCs) */
      break; /* cannot go further */
    }
    /* Get Max */
    /* vpi_trvs_get_time(vpiMaxTime, vc_trvs_hdl, time_p); */
    vpi_get_time(vc_trvs_hdl, time_p); /* Time of VC */
    vpi_get_value(vc_trvs_hdl, value_p); /* VC data */
  }
}
/* free handles */
vpi_free_object(...);

The code segment above declares an interactive access scheme, where only a limited history of values is provided by the tool (e.g. simulator). It then creates a Value Change (VC) traverse handle associated with an object whose handle is represented by var_handle but only after the object is loaded into memory first. It then creates a traverse handle, vc_trvs_hdl. With this traverse handle, it first calls vpi_control() to go to the minimum time where the value has changed and moves the handle (internal index) to that time by calling vpi_control() with a vpiMinTime argument. It then repeatedly calls vpi_control() with a vpiNextVC to move the internal index forward repeatedly until there is no value change left. vpi_get_time() gets the actual time where this VC is, and data is obtained by vpi_get_value().

The traverse and collection handles can be freed when they are no longer needed using vpi_free_object().

29.7.4.2 Jump Behavior

Jump behavior refers to the behavior of vpi_control() with a vpiTime property, vpiTrvsObj type, and a jump time argument. The user specifies a time to which he or she would like the traverse handle to jump, but the specified time may or not have value changes. In that case, the traverse handle shall point to the latest VC equal to or less than the time requested.

In the example below, the whole simulation run is from time 10 to time 65, and a variable has value changes at time 10, 15 and 50. If we create a value change traverse handle associated with this variable and try to jump to a different time, the result will be determined as follows:

- Jump to 12; traverse handle return time is 10.
- Jump to 15; traverse handle return time is 15.
- Jump to 65; traverse handle return time is 50.
- Jump to 30; traverse handle return time is 15.
- Jump to 0; traverse handle return time is 10.
- Jump to 50; traverse handle return time is 50.

If the jump time has a value change, then the internal index of the traverse handle will point to that time.
Therefore, the return time is exactly the same as the jump time.

If the jump time does not have a value change, and if the jump time is not less than the minimum time of the whole trace run, then the return time is aligned backward. If the jump time is less than the minimum time, then the return time will be the minimum time. In case the object has hold value semantics between the VCs such as static variables, then the return code of \texttt{vpi\_control()} (with a specified time argument to jump to) should indicate success. In case the time is greater than the trace maximum time, or we have an automatic object or an assertion or any other object that does not hold its value between the VCs then the return code should indicate failure (and the backward time alignment is still performed). In other words the time returned by the traverse object shall never exceed the trace maximum; the maximum point in the trace is not marked as a VC unless there is truly a value change at that point in time (see the example in this sub-section).

### 29.7.4.3 Dump off regions

When accessing a database file, it is likely that there are gaps along the value time-line where possibly the data recording (e.g. dumping from simulator) was turned off. In this case the starting point of that interval shall be marked as a VC if the object had a stored value before that time. \texttt{vpi\_control()} or \texttt{vpi\_goto()}, whether used to jump to that time or using next VC or previous VC traversal from a point before or after respectively, shall stop at that VC. Calling \texttt{vpi\_get\_value()} on the traverse object pointing to that VC shall have no effect on the value argument passed; the time argument will be filled with the time at that VC. \texttt{vpi\_get()} can be called in the form: \texttt{vpi\_get(vpiHasNoValue, <traverse handle>)} to return \texttt{TRUE} if the traverse handle has no value (i.e. pointing to the start of a dump off region) and \texttt{FALSE} otherwise.

There is, of course, another VC (from no recorded value to an actual recorded value) at the end of the dump off interval, if the end exits i.e. there is additional dumping performed and data for this object exits before the end of the trace. There are no VCs in between the two marking the beginning and end (if they exist); a move to the next VC from the start point leads to the end point.

#### 29.7.5 Sample code using (load and traverse) object collections

```c
p_vpi_extension reader; /* Pointer to reader VPI library */
vpiHandle scope; /* Some scope we are looking at */
vpiHandle var_handle; /* Object handle */
vpiHandle some_net; /* Handle of some net */
vpiHandle some_reg; /* Handle of some reg */
vpiHandle vc_trvs_hdl1; /* Traverse handle */
vpiHandle vc_trvs_hdl2; /* Traverse handle */
vpiHandle itr; /* Iterator */
vpiHandle loadCollection; /* Load collection */
vpiHandle trvsCollection; /* Traverse collection */

PLI_BYTE8 *datafile = "my_data_file"; /* data file */
p_vpi_time time_p; /* time */
/* Initialize the read interface: Post process mode, read from a file */
/* NOTE: Uses "toolX" library */
reader_p = vpi_load_extension("toolX", vpiAccessPostProcess, datafile);
if (reader_p == NULL) ... ; /* Not successful */

/* Get the scope using its name */
scope = reader_p->vpi_handle_by_name("top.m1.s1", NULL);
/* Create load collection */
loadCollection = reader_p->vpi_create(vpiObjCollection, NULL, NULL);
```

2 The word trace can be replaced by “simulation”; we use trace here for generality since a dump file can be generated by several tools.
/* Add data to collection: All the nets in scope */
/* ASSUMPTION: (waveform) tool "toolX" supports this navigation relationship */
itr = reader_p->vpi_iterate(vpiNet, scope);
while (var_handle = reader_p->vpi_scan(itr)) {
    loadCollection = reader_p->vpi_create(vpiObjCollection, loadCollection, var_handle);
}

/* Add data to collection: All the regs in scope */
/* ASSUMPTION: (waveform) tool supports this navigation relationship */
itr = reader_p->vpi_iterate(vpiReg, scope);
while (var_handle = reader_p->vpi_scan(itr)) {
    loadCollection = reader_p->vpi_create(vpiObjCollection, loadCollection, var_handle);
}

/* Initialize the load: focus only on the signals in the load collection: loadCollection */
reader_p->vpi_load_init(loadCollection, NULL, 0);

/* Demo scanning the load collection */
itr = reader_p->vpi_iterate(vpiMember, loadCollection);
while (var_handle = reader_p->vpi_scan(itr)) {
    ...
}

/* Load the data in one shot using load collection */
reader_p->vpi_read_load(loadCollection);

/* Application code here */
some_net = ...;
time_p = ...;
some_reg = ...;
....
vc_trvs_hdl1 = reader_p->vpi_handle(vpiTrvsObj, some_net);
vc_trvs_hdl2 = reader_p->vpi_handle(vpiTrvsObj, some_reg);
reader_p->vpi_control(vpiTime, vc_trvs_hdl1, time_p);
reader_p->vpi_control(vpiTime, vc_trvs_hdl1, time_p);
/* Data querying and processing here */
....

/* free handles*/
reader_p->vpi_free_object(...);

/* close data file */
reader_p->vpi_read_close(datafile);

The code segment above initializes the read interface for post process read access from file datafile. It then creates an object load collection loadCollection then adds to it all the objects in scope of type vpiNet and vpiReg (assuming this type of navigation is allowed in the tool). Load access is initialized and set to the objects listed in loadCollection. loadCollection can be iterated using vpi_iterate() to create the iterator and then using vpi_scan() to scan it assuming here that the waveform tool provides this navigation. The selected objects are then loaded in one shot using vpi_read_load() with loadCollection as argument. The application code is then free to obtain traverse handles for the loaded objects, and perform its querying and data processing as it desires.

If the user application wishes to access all (or a large number of) the objects in a specific scope (and maybe its subscopes) it is easier to call vpi_load_init_create() to create a load collection of all the objects in a
single shot. The code segment below shows a simple code segment that mimics the function of a $dumpvars
call to access data of all the regs in a specific scope and its subscopes and process the data.

```verbatim
p_vpi_extension reader_p; /* Reader library pointer */
vpiHandle big_scope; /* Some scope we are looking at */
vpiHandle obj_handle; /* Object handle */
vpiHandle obj_trvs_hdl; /* Traverse handle */
vpiHandle big_loadCollection; /* Load collection */
vpiHandle signal_iterator; /* Iterator for signals */
p_vpi_time time_p; /* time */

/* Initialize the read interface: Access data from simulator */
/* NOTE: Use default VPI (e.g. that of simulator application is running under */
reader_p = vpi_load_extension(NULL, NULL, vpiAccessLimitedInteractive);

if (reader_p == NULL) ...; /* Not successful */

/* Initialize the load access: data from (simulator) memory, for scope */
big_scope and its subscopes */
/* NOTE: Call marks load access AND creates collection for all the objects in */
the scope */
big_loadCollection = vpi_load_init_create(NULL, big_scope, 0);

if (big_loadCollection == NULL) {
    /* unable to create collection */
}

/* Load the data in one shot using load collection */
vpi_read_load(big_loadCollection);

/* Application code here */
/* Obtain handle for all the regs in scope */
signal_iterator = vpi_iterate(vpiReg, big_scope);

/* Data querying and processing here */
while ( (obj_handle = vpi_scan(signal_iterator)) != NULL ) {
    assert(vpi_get(vpiType, obj_handle) == vpiReg);
    /* Create a traverse handle for read queries */
    obj_trvs_hdl = vpi_handle(vpiTrvsObj, obj_handle);
    time_p = ...; /* some time */
    vpi_control(vpiTime, obj_trvs_hdl, time_p);
    /* Get info at time */
    vpi_get_value(obj_trvs_hdl, value_p); /* Value */
    vpi_printf("....");
}
/* free handles*/
vpi_free_object(...);
```

### 29.7.6 Object-based traversal

Object based traversal can be performed by creating a traverse handle for the object and then moving it back
and forth to the next or previous Value Change (VC) or by performing jumps in time. A traverse object handle
for any object in the design can be obtained by calling vpi_handle() with a vpiTrvsObj type, and an
object vpiHandle. This is the method described in Section 29.7.4, and used in all the code examples thus far.

Using this method, the traversal would be object-based because the individual object traverse handles are cre-
ted, and then the application can query the (value, time) pairs for each VC. This method works well when the
design is being navigated and there is a need to access the (stored) data of any individual object.
29.7.7 Time-ordered traversal

Alternatively, we may wish to do a time-ordered traversal i.e. a time-based examination of values of several objects. We can do this by using a collection. We first create a traverse collection of type vpiTrvsCollection of the objects we are interested in traversing from the design object collection of type vpiObjCollection using vpi_handle() with a vpiTrvsCollection type and collection handle argument. We can then call vpi_control() or vpi_goto() on the traverse collection to move to next or previous or do jump in time for the collection as a whole. A move to next (previous) VC means move to the next (previous) earliest VC among the objects in the collection; any traverse handle that does not have any VC is ignored. A jump to a specific time aligns the handles of all the objects in the collection (as if we had done this object by object, but here it is done in one-shot for all elements).

We can choose to loop in time by incrementing the time, and doing a jump to those time increments. This is shown in the following code snippet.

```c
vpiHandle loadCollection = ...;
vpiHandle trvsCollection;
BEGIN_TIME;
/* Obtain (create) traverse collection from load collection */
trvsCollection = vpi_handle(vpiTrvsCollection, loadCollection);
/* Loop in time: increments of 100 units */
for (i = 0; i < 1000; i = i + 100) {
    BEGIN_TIME;
    /* Go to point in time */
    vpi_control(vpiTime, trvsCollection, time_p);
    END_TIME;
}
```

Alternatively we may wish to go to the next VC of the traverse collection defined to be the VC with the smallest time among the VCs in the traverse object in the collection; again traverse objects with no VCs are ignored. This is shown in the following code snippet.

```c
vpiHandle loadCollection = ...;
vpiHandle trvsCollection;
vpiHandle vc_trvs1_hdl, vc_trvs2_hdl;
BEGIN_TIME;
BEGIN_TIME;
/* Create traverse collection */
BEGIN_TIME;
BEGIN_TIME;
BEGIN_TIME;
trvsCollection = vpi_handle(vpiTrvsCollection, loadCollection);
vc_trvs1_hdl = ... ; /* some element of trvsCollection */
vc_trvs2_hdl = ... ;/* another element of trvsCollection */

BEGIN_TIME;
BEGIN_TIME;
BEGIN_TIME;
BEGIN_TIME;
BEGIN_Time
```
By testing the traverse handle time of any element against the collection VC time we can find out if the element has a VC at that time or not. This is shown in the last segment of the code sample above.

Alternatively, we may wish to get a new collection returned of all the objects that have a value change at the given time we moved the traverse collection to. In this case \texttt{vpi\_control()} is replaced with a call to \texttt{vpi\_goto()}. The latter returns a new collection with all the traverse objects that have a VC at that time. This is shown in the code snippet that follows.

```c
...
  vpiHandle vctrvsCollection; /* collection for the objects with VC */
  vpiHandle itr; /* collection member iterator */
...
/* Go to earliest next VC in the collection */
for (;;) { /* for all collection VCs in time */
  vctrvsCollection = vpi_goto(vpiNextVC, trvsCollection);
  if (vctrvsCollection == NULL) {
    /* failure (e.g. already at MaxTime or no more VCs) */
    break; /* cannot go further */
  }
/* create iterator then scan the VC collection */
  itr = vpi_iterate(vpiMember, vctrvsCollection);
  while (vc_trvs1_hdl = vpi_scan(itr)) {
    /* Element has a VC */
    vpi_get_value(vc_trvs1_hdl, value_p); /* VC data */
    /* Do something at this VC point */
    ...
  }
...}
```

### 29.8 Unloading the data

Once the user application is done with accessing the data it had loaded, it shall call \texttt{vpi\_read\_unload()} to unload the data from (active) memory. Failure to call this unload may affect the tool performance and capacity and its consequences are not addressed here since managing the data caching and memory hierarchy is left to tool implementation.

Calling \texttt{vpi\_read\_unload()} before releasing (freeing) traverse (collection) handles that are manipulating the data using \texttt{vpi\_free\_object()} is not recommended practice by users; the behavior of traversal using \texttt{existing} handles is not defined here. It is left up to tool implementation to decide how best to handle this. Tools shall, however, prevent creation of new traverse handles by returning the appropriate fail codes in the respective creation routines; this situation is similar to attempting to create traverse handles before doing any data loads with \texttt{vpi\_read\_load()}, and shall be treated in a similar fashion.

### 29.9 Reading data from multiple databases and/or different read library providers

The VPI routine \texttt{vpi\_load\_extension()} is used to load VPI extensions. Such extensions include reader libraries from such tools as waveform viewers. \texttt{vpi\_load\_extension()} shall return a pointer to a function pointer structure with the following definition.

```c
typedef struct {
  void *user_data;       /* Attach user data here if needed */
  /* Below this point user application MUST NOT modify any values */
  size_t struct_size;    /* Must be set to sizeof(s_vpi_extension) */
  long struct_version;   /* Set to 1 for SystemVerilog 3.1a */
  PLI_BYTE8 *extension_version;
};
```
PLI_BYTE8 *extension_name;

/* One function pointer for each of the defined VPI routines:
- Each function pointer has to have the correct prototype */

... PLI_INT32 (*vpi_chk_error)(error_info_p);
... PLI_INT32 (*vpi_vprintf)(PLI_BYTE8 *format, ...);
...
} s_vpi_extension, *p_vpi_extension;

Subsequent versions of the s_vpi_extension structure shall only extend it by adding members at the end; previously existing entries must not be changed, removed, or re-ordered in order to preserve backward compatibility. The struct_size entry allows users to perform basic sanity checks (e.g. before type casting), and the struct_version permits keeping track and checking the version of the s_vpi_extension structure. The structure also has a user_data field to give users a way to attach data to a particular load of an extension if they wish to do so.

The structure shall have an entry for every VPI routine. If a particular extension does not support a specific VPI routine, then it shall still have an entry (with the correct prototype), and a dummy body that shall always have a return (consistent with the VPI prototype) to signify failure (i.e. NULL or FALSE as the case may be). The routine call must also raise the appropriate VPI error, which can be checked by vpi_chk_error(), and/or automatically generate an error message in a manner consistent with the specific VPI routine.

If tool providers want to add their own implementation extensions, those extensions must only have the effect of making the s_vpi_extension structure larger and any non-standard content must occur after all the standard fields. This permits applications to use the pointer to the extended structure as if it was a p_vpi_extension pointer, yet still allow the applications to go beyond and access or call tool-specific fields or routines in the extended structure. For example, a tool extended s_vpi_extension could be:

typedef struct {
    /* inline a copy of s_vpi_extension */
    /* begin */
    void *user_data;
    ...
    /* end */
    /* “toolZ” extension with one additional routine */
    int (*toolZfunc)(int);
} s_toolZ_extension, *p_toolZ_extension;

An example of use of the above extended structure is as follows:

p_vpi_extension h;
p_toolZ_extension h2;

h = vpi_load_extension(“toolZ”, <args>);
if ( h && !(strcmp(h->extension_version, “...”)
     && strcmp(h->extension_name, “toolZ”) ) {
    h2 = (p_toolZ_extension) h;
    /* Can now use h2 to access all the VPI routines, including toolZ’s
    ‘toolZfunc’ */
    ...
}

The SystemVerilog tool the user application is running under is responsible for loading the appropriate extension, i.e. the reader API library in the case of the read API. The extension name is used for this purpose, following a specific policy, for example, this extension name can be the name of the library to be loaded. Once
the reader API library is loaded all VPI function calls that wish to use the implementation in the library shall be performed using the returned p_vpi_extension pointer as an indirect to call the function pointers specified in s_vpi_extension or the extended vendor specific structure as described above. Note that, as stated earlier, in the case the application is using the default routine implementation (i.e. the ones provided by the tool (e.g. simulator) it is running under) then the de-reference through the pointer is not necessary.

Multiple databases can be opened for read simultaneously by the application. After a vpi_load_extension() call, a top scope handle can be created for that database to be used later to derive any other handles for objects in that database. An example of multiple database access is shown below. In the example, scope1 and scope2 are the top scope handles used to point into database1 and database2 respectively and perform the processing (comparing data in the two databases for example).

```c
p_vpi_extension reader_pX; /* Pointer to reader library function struct */
p_vpi_extension reader_pY; /* Pointer to reader library function struct */

vpiHandle scopel, scope2; /* Some scope we are looking at */

vpiHandle var_handle; /* Object handle */

vpiHandle some_net; /* Handle of some net */

vpiHandle some_reg; /* Handle of some reg */

vpiHandle vc_trvs_hdl1; /* Traverse handle */

vpiHandle vc_trvs_hdl2; /* Traverse handle */

vpiHandle itr; /* Iterator */

vpiHandle loadCollection1, loadCollection2; /* Load collection */

vpiHandle trvsCollection1, trvsCollection2; /* Traverse collection */

p_vpi_extension reader_pX; /* Pointer to reader library function struct */
p_vpi_extension reader_pY; /* Pointer to reader library function struct */

vpiHandle scopel, scope2; /* Some scope we are looking at */

vpiHandle var_handle; /* Object handle */

vpiHandle some_net; /* Handle of some net */

vpiHandle some_reg; /* Handle of some reg */

vpiHandle vc_trvs_hdl1; /* Traverse handle */

vpiHandle vc_trvs_hdl2; /* Traverse handle */

vpiHandle itr; /* Iterator */

vpiHandle loadCollection1, loadCollection2; /* Load collection */

vpiHandle trvsCollection1, trvsCollection2; /* Traverse collection */

p_vpi_time time_p; /* time */

PLI_BYTE8 *datafile1 = "database1"; /* data file 1 */
PLI_BYTE8 *datafile2 = "database2"; /* data file 2 */

/* Initialize the read interface: Post process mode, read from a file */
/* NOTE: Use library from "toolX" */
reader_pX = vpi_load_extension("toolX", datafile1, vpiAccessPostProcess);
/* Get the scope using its name */
/* NOTE: scope handle comes from file database: datafile1 */
scopel = reader_pX->vpi_handle_by_name("top.m1.s1", NULL);

/* Initialize the read interface: Post process mode, read from a file */
/* NOTE: Use library from "toolY" */
reader_pY = vpi_load_extension("toolY", datafile2, vpiAccessPostProcess);
/* Get the scope using its name */
/* NOTE: scope handle comes from file database: datafile2 */
scope2 = reader_pY->vpi_handle_by_name("top.m1.s1", NULL);

/* Create load collections */
loadCollection1 = reader_pX->vpi_create(vpiObjCollection, NULL, NULL);
loadCollection2 = reader_pY->vpi_create(vpiObjCollection, NULL, NULL);

/* Add data to collection1: All the nets in scopel,
data comes from database1 */
/* ASSUMPTION: (waveform) tool supports this navigation relationship */
itr = reader_pX->vpi_iterate(vpiNet, scopel);
while (var_handle = reader_pX->vpi_scan(itr)) {
  loadCollection1 = reader_pX->vpi_create(vpiObjCollection, loadCollection1, var_handle);
}

/* Add data to collection2: All the nets in scope2,
data comes from database2 */
/* ASSUMPTION: (waveform) tool supports this navigation relationship */
itr = reader_pY->vpi_iterate(vpiNet, scope2);
```
while (var_handle = reader_pY->vpi_scan(itr)) {
    loadCollection2 = reader_pY->vpi_create(vpiObjCollection, loadCollection2, var_handle);
}

/* Initialize the load: focus only on the signals in the load collection: loadCollection */
reader_pX->vpi_load_init(loadCollection1, NULL, 0);
reader_pY->vpi_load_init(loadCollection2, NULL, 0);

/* Demo: Scan the load collection */
itr = reader_pX->vpi_iterate(vpiMember, loadCollection1);
while (var_handle = reader_pX->vpi_scan(itr)) {
    ...
}
itr = reader_pY->vpi_iterate(vpiMember, loadCollection2);
while (var_handle = reader_pY->vpi_scan(itr)) {
    ...
}

/* Load the data in one shot using load collection */
reader_pX->vpi_read_load(loadCollection1);
reader_pY->vpi_read_load(loadCollection2);

/* Application code here: Access Objects from database1 or database2 */
some_net = ...;
time_p = ...;
some_reg = ...;
....
/* Data querying and processing here */
....

/* free handles*/
reader_pX->vpi_free_object(...);
reader_pY->vpi_free_object(...);

/* close data files */
reader_pX->vpi_read_close(datafile1);
reader_pY->vpi_read_close(datafile2);

29.10 Reader VPI routines

29.10.1 Extensions to existing routines

This section describes the extensions to existing VPI routines. Most are obvious and shown in Table 29-1. vpi_control() is described here again for clarity.

vpi_control()

**Synopsis:** Try to move value change traverse index to min, max or specified time. If the request is for a next or previous VC and there is none (for collection this means no VC for any object) a fail is returned, otherwise a success is returned. If there is no value change at specified time in a jump, then the value change traverse index is aligned based on the jump behavior defined earlier in Section 29.7.4.2, and the time will be updated based on the aligned traverse point. If there is a value change occurring at the requested time, then the value change traverse index is moved to that tag with success return, otherwise if the object does not have hold semantics a fail is returned. In the case of a collection, a fail is only returned
when none of the objects in its group can return a true.

**Syntax:**

```c
vpi_control(vpiType prop, vpiHandle obj, p_vpi_time time_p)
```

**Returns:** PLI_INT32, 1 for success, 0 for fail.

**Arguments:**

- `vpiType prop`:
  - `vpiMinTime`: Goto the minimum time of traverse (collection) handle.
  - `vpiMaxTime`: Goto the maximum time of traverse (collection) handle.
  - `vpiTime`: Jump to the time specified in `time_p`.
- `vpiHandle obj`: Handle to a traverse object (collection) of type `vpitrvsObj`
- `p_vpi_time time_p`: Pointer to a structure containing time information. Used only if `prop` is of type `vpiTime`, otherwise it is ignored.

**Related routines:** `vpi_goto()`. Difference is that `vpi_goto()` can operate only on traverse collection handles, and returns a new traverse collection for the objects that have a VC at the time it moves to.

### 29.10.2 Additional routines

This section describes the additional VPI routines in detail.

**vpi_read_getversion()**

**Synopsis:** Get the reader version.

**Syntax:**

```c
vpi_read_getversion()
```

**Returns:** PLI_BYTE8*, for the version string

**Arguments:** None

**Related routines:** None

**vpi_load_extension()**

**Synopsis:** Load specified VPI extension. For the reader, initialize the reader with access mode, and specify the database file if used.

**Syntax:**

```c
vpi_load_extension(PLI_BYTE8 *extension_name, ...) in its general form
vpi_load_extension( PLI_BYTE8 *extension_name,
                   PLI_BYTE8 *filename,
                   vpiType mode, ...) for the reader extension
```

**Returns:** PLI_INT32, 1 for success, 0 for fail.

**Arguments:**

- `PLI_BYTE8 *extension_name`: Extension name of the extension library to be loaded.
  - . . . : Contains all the additional arguments. For the reader extension these are:
  - `PLI_BYTE8 *filename`: Data file.
  - `vpiType mode`:
    - `vpiAccessLimitedInteractive`: Access data in tool memory, with limited history. The tool shall at least have the current time value, no history is required.
    - `vpiAccessInteractive`: Access data interactively. Tool shall keep value history up to the current time.
  - . . . : Additional arguments if required by specific reader extensions.

**Related routines:** None.

**vpi_read_close()**

**Synopsis:** Close the datafile if open.

**Syntax:**

```c
vpi_read_close(vpiType prop, PLI_BYTE8* filename)
```

**Returns:** PLI_INT32, 1 for success, 0 for fail.

**Arguments:**

- `vpiType prop`:
PLI_BYTE8* filename: Data file.

Related routines: None.

**vpi_load_init()**

Synopsis: Initialize the load access to scope and/or collection of objects.

Syntax: `vpi_load_init(vpiHandle loadCollection, vpiHandle scope, PLI_INT32 level)`

Returns: PLI_INT32, 1 for success, 0 for fail.

Arguments:
- `vpiHandle loadCollection`: Load collection of type vpiObjCollection, a collection of design objects.
- `vpiHandle scope`: Scope of the load.
- `PLI_INT32 level`: If 0 then enables load access to scope and all its subscopes, 1 means just the scope.

Related routines: None.

**vpi_load_init_create()**

Synopsis: Initialize the load access scope and/or collection of objects. It returns a load collection of all the (valued) design objects in access scope and/or access collection.

Syntax: `vpi_load_init_create(vpiHandle loadCollection, vpiHandle scope, PLI_INT32 level)`

Returns: `vpiHandle` of type vpiObjCollection for success, NULL for fail.

Arguments:
- `vpiHandle loadCollection`: Load collection of type vpiObjCollection, a collection of design objects.
- `vpiHandle scope`: Scope of the load.
- `PLI_INT32 level`: If 0 then enables load access to scope and all its subscopes, 1 means just the scope.

Related routines: vpi_load_init().

**vpi_trvs_get_time()**

Synopsis: Retrieve the time of the object or collection of objects traverse handle.

Syntax: `vpi_trvs_get_time(vpiType prop, vpiHandle obj, p_vpi_time time_p)`

Returns: PLI_INT32, 1 for success, 0 for fail.

Arguments:
- `vpiType prop`:
  - `vpiMinTime`: Gets the minimum time of traverse object or traverse collection. Returns failure if traverse object or collection has no value changes and `time_p` is not modified.
  - `vpiMaxTime`: Gets the maximum time of traverse object or traverse collection. Returns failure if traverse object or collection has no value changes and `time_p` is not modified.
  - `vpiTime`: Gets the time where traverse handle points. Returns failure if traverse object or collection has no value changes and `time_p` is not modified. In the case of a collection, it returns success (and `time_p` is updated) only when all the traverse objects in the collection are pointing to the same time, otherwise returns failure and `time_p` is not modified.
  - `vpiNextVC`: Gets the time where traverse handle points next. Returns failure if traverse object or collection has no next VC and `time_p` is not modified. In the case of a collection, it returns success when any traverse object in the collection has a next VC, `time_p` is updated with the smallest next VC time.
  - `vpiPrevVC`: Gets the time where traverse handle previously points. Returns failure if traverse object or collection has no previous VC and `time_p` is not modified. In the case of a collection, it returns success when any traverse object in the collection has a previous VC, `time_p` is updated with the largest previous VC time.

- `vpiHandle obj`: Handle to a traverse object of type vpiTrvsObj or a traverse collection of
type vpiTrvsCollection.
    p_vpi_time time_p: Pointer to a structure containing the returned time information.

Related routines: vpi_get_time(). Difference is that vpi_trvs_get_time() is more general in that it allows an additional vpiType argument to get the min/max/prev/next current time of handle.
    vpi_get_time() can only get the current time of traverse handle.

vpi_read_load()
Synopsis: Load the data of the given object into memory for data access and traversal if object is an object handle; load the whole collection (i.e. set of objects) if passed handle is a load collection of type vpiObjCollection.
Syntax: vpi_read_load(vpiHandle h)
Returns: PLI_INT32, 1 for success of loading (all) object(s) (in collection), 0 for fail of loading (any) object (in collection).
Arguments:
    vpiHandle h: Handle to a design object (of any valid type) or object collection of type vpiObjCollection.
Related routines: None

vpi_read_unload()
Synopsis: Unload the given object data from (active) memory if object is an object handle, unload the whole collection if passed object is a collection of type vpiObjCollection. See Section 29.8 for a description of data unloading.
Syntax: vpi_read_unload(vpiHandle h)
Returns: PLI_INT32, 1 for success, 0 for fail.
Arguments:
    vpiHandle h: Handle to an object or collection (of type vpiObjCollection).
Related routines: None.

vpi_create()
Synopsis: Create or add to a load or traverse collection.
Syntax: vpi_create(vpiType prop, vpiHandle h, vpiHandle obj)
Returns: vpiHandle of type vpiObjCollection for success, NULL for fail.
Arguments:
    vpiType prop:
        vpiObjCollection: Create (or add to) load (vpiObjCollection) or traverse (vpiTrvsCollection) collection.
    vpiHandle h: Handle to a (object) traverse collection of type (vpiObjCollection)
    vpiTrvsCollection, NULL for first call (creation)
    vpiHandle obj: Handle of object to add, NULL if for first time creation of collection.
Related routines: None.

vpi_goto()
Synopsis: Try to move value change traverse index of members of collection to min, max or specified time. If the request is for a next or previous VC and there is no VC for any object in collection a NULL is returned signifying fail, otherwise a new collection with all objects that have a VC at the time we moved to is returned signifying success. If there is no value change at specified time in a jump, then the value change traverse index for each object is aligned based on the jump behavior defined earlier in Section 29.7.4.2, and its time will be updated based on the aligned traverse point. A fail (i.e. NULL collection) is only returned when none of the objects in its group can return an individual success. See vpi_control() for a more detailed description of the semantics of individual traverse object handles.
Syntax: vpi_goto(vpiType prop, vpiHandle obj, p_vpi_time time_p)
Returns: vpiHandle of type vpiObjCollection for success, NULL for fail.
Arguments:
    vpiType prop:
        vpiMinTime: Goto the minimum time of traverse collection handle.
vpiMaxTime: Goto the maximum time of traverse collection handle.

vpiTime: Jump to the time specified in time_p.

vpiHandle obj: Handle to a traverse object of type vpiTrvsCollection.

p_vpi_time time_p: Pointer to a structure containing time information. Used only if prop is of type vpiTime, otherwise it is ignored.

Related routines: vpi_control(). Difference is that vpi_goto() can operate only on traverse collection handles, and returns a new traverse collection for the objects that have a VC at the time it moves to.

vpi_filter()

Synopsis: Filter a general collection, a traversable object collection, or traverse collection according to a specific criterion. Return a collection of the handles that meet the criterion. Original collection is not changed.

Syntax: vpi_filter(vpiHandle h, PLI_INT32 ft, PLI_INT32 flag)

Returns: vpiHandle of type vpiObjCollection for success, NULL for fail.

Arguments:

vpiHandle h: Handle to a collection of type vpiCollection, vpiObjCollection or vpiTrvsCollection

PLI_INT32 ft: Filter criterion, any vpiType or a VPI Boolean property.

PLI_INT32 flag: Flag to indicate whether to match criterion (if set to TRUE), or not (if set to FALSE).

Related routines: None.
