30.1 Instance

**Instance**

- array member
  - bool: vpiArray
- cell
  - bool: vpiCellInstance
- default net type
  - int: vpiDefNetType
- definition location
  - int: vpiDefLineNo
  - str: vpiDefFile
- definition name
  - str: vpiDefName
- delay mode
  - int: vpiDefDelayMode
- name
  - str: vpiName
  - str: vpiFullName
- protected
  - bool: vpiProtected
- timeprecision
  - int: vpiTimePrecision
- timeunit
  - int: vpiTimeUnit
- unconnected drive
  - int: vpiUnconnDrive
- Configuration
  - str: vpiLibrary
  - str: vpiCell
  - str: vpiConfig
- default lifetime
  - bool: vpiAutomatic
- top
  - bool: vpiTop
- compile unit
  - bool: vpiUnit

**Instance Items**

- program
- program array
- interface
- interface array
- task func
- scope
- net
- net array
- variables
  - array var
  - reg
  - reg array
- named event
- named event array
- process
- parameter
- def param
- param assign
- spec param
- clocking block
- concurrent assertions
- Typespec
NOTES
1. Top-level instances shall be accessed using \texttt{vpi\_iterate()} with a NULL reference object.
2. Passing a NULL handle to \texttt{vpi\_get()} with types \texttt{vpi\_Time\_Precision} or \texttt{vpi\_Time\_Unit} shall return the smallest time precision of all instances in the design.
3. If an instance is an element within an array, the \texttt{vpi\_Index} transition is used to access the index within the array. If the instance is not part of an array, this transition shall return NULL.
4. Compilation units are represented as packages that have a \texttt{vpi\_Unit} property set to TRUE. Such implicitly declared packages shall have implementation dependent names.
**30.2 Interface**

NOTE

All interfaces are instances and all relations and properties in the Instances diagram also apply.

**30.3 Program**

NOTE

All programs are instances and all relations and properties in the Instances diagram also apply.
30.4 Module (supersedes IEEE 1364-2001 26.6.1)

NOTE to reviewers leave all relations here, as the arrow back is different than in the instance diagram ie most items have two possible container relations:

vpiModule
vpiInstance

NOTES

1. **vpiModule** will return a module if the object is inside a module instance, otherwise NULL;

2. **vpiInstance** will always return the immediate instance (package, module, program or interface) in which the object is instantiated

3. vpiMemory will return array variable objects rather than vpiMemory objects. The IEEE 1364 committee is currently making a similar update to the Verilog VPI (refer to note 3 in IEEE 1364-2001, section 26.6.9)
30.5 Modport

![Diagram of interface, modport, and io decl]

- `-> name`
  - `str: vpiName`

30.6 Interface tf decl

![Diagram of interface tf decl, task, and function]

- `-> access type`
  - `int: vpiAccessType`
  - `vpiForkJoin`
  - `vpiExtern`

**NOTE**

`vpiIterate(vpiTaskFunc)` can return more than one task/function declaration for modport tasks/functions with an access type of `vpiForkJoin`, because the task or function can be imported from multiple module instances.
### 30.7 Ports (supercedes IEEE 1364-2001 26.6.5)

```
instance          ports
    port
        vpiParent
        vpiBit
        port bit

- > connected by name
  - bool: vpiConnByName
- > delay (mipd)
  - vpi_get_delays()
  - vpi_put_delays()
- > direction
  - int: vpiDirection
- > explicitly named
  - bool: vpiExplicitName
- > index
  - int: vpiPortIndex
- > name
  - str: vpiName
- > port type
  - int: vpiPortType
- > scalar
  - bool: vpiScalar
- > size
  - int: vpiSize
- > vector
  - bool: vpiVector
expr
vpiHighConn
vpiLowConn
refobj
```

### NOTES

1. **vpiPortType** shall be one of the following three types: **vpiPort**, **vpiInterfacePort**, and **vpiModportPort**. Port type depends on the formal, not on the actual.

2. **vpi_get_delays**, **vpi_put_delays** delays shall not be applicable for **vpiInterfacePort**.

3. **vpiHighConn** shall indicate the hierarchically higher (closer to the top module) port connection.

4. **vpiLowConn** shall indicate the lower (further from the top module) port connection.

5. **vpiLowConn** of a **vpiInterfacePort** shall always be **vpiRefObj**.

6. Properties scalar and vector shall indicate if the port is 1 bit or more than 1 bit. They shall not indicate anything about what is connected to the port.

7. Properties index and name shall not apply for port bits.

8. If a port is explicitly named, then the explicit name shall be returned. If not, and a name exists, then that name shall be returned. Otherwise, NULL shall be returned.

9. **vpiPortIndex** can be used to determine the port order. The first port has a port index of zero.

10. **vpiHighConn** and **vpiLowConn** shall return NULL if the port is not connected.

11. **vpiSize** for a null port shall return 0.
30.8 Ref Obj

Examples

These objects are newly defined objects needed for supporting the full connectivity through ports where the ports are vpiInterface or vpiModport or any object inside modport or interface.

RefObjs are dummy objects and they always have a handle to the original object.

```verilog
interface simple ()
    logic req, gnt;
    modport slave (input req, output gnt);
    modport master (input gnt, output req);
}
module top()
    interface simple i;
    child1 i1(i);
    child2 i2(i.master);
endmodule
```
Accellera

/******************************************************************************
for port of i1,
    vpiHighConn = vpiRefObj where vpiRefObjType = vpiInterface

for port of i2,
    vpiHighConn = vpiRefObj where vpiFullType = vpiModport
******************************************************************************/
module child1(interface simple s)
    cl c_1(s);
    cl c_2(s.master);
endmodule

/******************************************************************************
for port of child1,
    vpiLowConn = vpiRefObj where vpiRefObjType = vpiInterface

for that refObj,
    vpiPort is = port of child1.
    vpiPortInst is = s, s.master
    vpiInterfaceConn is = i.

for port of c_1:
    vpiHighConn is a vpiRefObj, where full type is vpiInterface.

for port of c_2:
    vpiHighConn is a vpiRefObj, where full type is vpiModport.
/******************************************************************************/

- packed array
- bool: vpiPacArray
- scalar
- bool: vpiScalar
- visibility
- bool: vpiVisibility
- vector
- bool: vpiVector
NOTES

1. A var select is a word selected from a variable array.

2. The boolean property \texttt{vpiArray} shall be \texttt{TRUE} if the variable handle references an array of variables, and \texttt{FALSE} otherwise. If the variable is an array, iterate on \texttt{vpiVarSelect} to obtain handles to each variable in the array.

3. To obtain the members of a union and structure, see the relations in section \ref{sec:struct-union-relations}.

4. The range relation is valid only when \texttt{vpiArray} is \texttt{TRUE}. When applied to array vars this relation returns only unpacked ranges. When applied to logic and bit variables, it returns only the packed ranges.

5. \texttt{vpi\_handle(vpiIndex, var\_select\_handle)} shall return the index of a var select in a 1-dimensional array. \texttt{vpi\_iterate(vpiIndex, var\_select\_handle)} shall return the set of indices for a var select in a multidimensional array, starting with the index for the var select and working outward.

6. \texttt{vpiLeftRange} and \texttt{vpiRightRange} shall only apply if \texttt{vpi\_MultiArray} is \texttt{FALSE}, i.e., if the array is not multidimensional.

7. A variable handle of type \texttt{vpiArrayVar} represents an unpacked array. The range iterator for array vars returns only the unpacked ranges for the array.

8. If the variable has an initialization expression, the expression can be obtained from \texttt{vpi\_handle(vpi\_Expr, var\_handle)}.

9. \texttt{vpi\_Size} for a variable array shall return the number of variables in the array. For non-array variables, it shall return the size of the variable in bits. For unpacked structures and unions the size returned indicates the number of fields in the structure or union.

10. \texttt{vpi\_Size} for a var select shall return the number of bits in the var select. This applies only for packed var select.

11. Variables whose boolean property \texttt{vpi\_Array} is \texttt{TRUE} do not have a value property.

12. \texttt{vpi\_Bit} iterator applies only for logic, bit, packed struct, and packed union variables.

13. \texttt{vpi\_handle(vpiIndex, var\_bit\_handle)} shall return the bit index for the variable bit. \texttt{vpi\_iterate(vpiIndex, var\_bit\_handle)} shall return the set of indices for a multidimensional variable bit select, starting with the index for the bit and working outward.

14. \texttt{cb\_SizeChange} will be applicable only for dynamic and associative arrays. If both value and size change, the size change callback will be invoked first. This callback fires after size change occurs and before any value changes for that variable. The value in the callback is new size of the array.

15. The property \texttt{vpi\_RandType}, returns the current randomization type for the variable, which can be one of \texttt{vpi\_Rand}, \texttt{vpi\_RandC}, and \texttt{vpi\_NotRand}.

16. \texttt{vpi\_IsRandomized} is a property to determine whether a random variable is currently active for randomization.

17. When the \texttt{vpi\_Member} property is \texttt{TRUE}, it indicates that the variable is a member of a parent struct or union variable. See also relations in section \ref{sec:struct-union-relations}.

18. If a variable is an element of an array, the \texttt{vpi\_Index} iterator will return the indexing expressions that select that specific variable out of the array.

19. Note that:
   ```
   logic var == reg
   var bit var == reg bit
   array var == reg array
   ```
30.10 Var Select (supercedes IEEE 1364-2001 26.6.8)

```
variable[expr]

var select

variable[expr]

vpiParent

->constant selection
   bool: vpiConstantSelect
->name
   str: vpiName
   str: vpiFullName
->valid
   vpiValid
->size
   int: vpiSize
->value
   vpi_get_value()
   vpi_put_value()

expr

vpiIndex
```
30.11 Typespec

NOTES

1. Typespec to typespec relation is used when the vpiTypedefType is "vpiTypedef", which will be the case for type aliases, for example, typedef a b;
2. If the type of a type is \texttt{vpiStruct} or \texttt{vpiUnion}, then you can iterate over numbers to obtain the structure of the user-defined type. For each member the typespec relation from the member will detail its type.

3. The name of a typedef may be the empty string if the typedef is representing the type of a typedef field defined inline rather than via a typedef. For example:

```c
typedef struct {
    struct
        int a;
    } B;
}
```

The typedef C has \texttt{vpiTypedefType vpiStruct}, a single field named B with \texttt{vpiTypedefType vpiStruct}. Obtaining the typedef of field B, you will obtain a typedef with no name and a single field, named "a" with \texttt{vpiTypedefType of vpiInt}. 
30.12 Variable Drivers and Loads (supercedes IEEE 1364-2001 26.6.23)

**NOTES**

1. **vpiDrivers/Loads** for a structure, union, or class variable will include the following:
   - Driver/Load for the whole variable
   - Driver/Load for any bit/part select of that variable
   - Driver/Load of any member nested inside that variable

2. **vpiDrivers/Loads** for any variable array should include the following:
   - Driver/Load for entire array/vector or any portion of an array/vector to which a handle can be obtained.

30.13 Instance Arrays (supercedes IEEE 1364-2001 26.6.2)

**NOTE**

Param assignments can only be obtained from non-primitive instance arrays.
30.14 Scope (supersedes IEEE 1364-2001 26.6.3)

NOTE

1: Unnamed scopes shall have valid names, though tool dependent.

2: The vpiImport iterator shall return all objects imported into the current scope via import statements. Note that only objects actually referenced through the import shall be returned, rather than items potentially made visible as a result of the import. Refer to section 18.2.2 for more details.
30.15 IO Declaration (supercedes IEEE 1364-2001 26.6.4)

**NOTE**

`vpiDirection` returns `vpiRef` for pass by ref ports.
30.16 Clocking Block

Accellera
30.17 Class Object Definition

NOTE

1. **ClassDefn** handle is a new concept. It does not correspond to any **vpiUserDefined** (class object) in the design. Rather it represents the actual type definition of a class.

2. Should not call **vpi_get_value/vpi_put_value** on the non-static variables obtained from the class definition handle.

3. Iterator to constraints returns only normal constraints and not inline constraints.

4. To get constraints inherited from base classes, you will need to traverse the extend relation to obtain the base class.

5. The **vpiDerivedClasses** iterator returns all the classes derived from the given class.

6. The relation to **vpiExtend** exists whenever a one class is derived from another class (ref Section 11.12). The relation from extend to classDefn provides the base class. The iterators from extend to param assign and arguments provide the parameters and arguments used in constructor chaining (ref Section 11.16 and 11.23)
30.18 Constraint, constraint ordering, distribution,
30.19 Constraint expression
30.20 Class Variables

NOTES

1. `vpiWaiting/Process` iterator on mailbox/semaphores will show the processes waiting on the object:
   - Waiting process means either frame or task/function handle.

2. `vpiMessage` iterator shall return all the messages in a mailbox.

3. `vpiClassDefn` returns the ClassDefn which was used to create the handle. `vpiActualDefn` returns the ClassDefn that handle object points to when the query is made. The difference can be seen in the example below:
   ```
   class Packet
   ...
   endclass : Packet
   
   class LinkedPacket extends Packet
   ...
   endclass : LinkedPacket
   
   LinkedPacket l = new;
   Packet p = l;
   ```
   In this example, the `vpiClassDefn` of variable "p" is Packet, but the `vpiActualDefn` is "LinkedPacket".

4. `vpiClassDefn/vpiActualDefn` both shall return NULL for built-in classes.
30.21 Structure/Union

\[\text{struct var} \quad \text{union var} \quad \text{vpiParent} \quad \text{vpiMembers} \quad \text{variables}\]

\text{\textbf{NOTES}}

\textbf{vpi_get_value/vpi_put_value} cannot be used to access values of entire unpacked structures and unpacked unions.
30.22 Named Events (supercedes IEEE 1364-2001 26.6.11)

The new iterator (vpiWaitingProcess) returns all waiting processes, identified by their frame, for that namedEvent.

vpi_iterate(vpiIndex, named_event_handle) shall return the set of indices for a named event within an array, starting with the index for the named event and working outward. If the named event is not part of an array, a NULL shall be returned.
30.23 Task, Function Declaration (supercedes IEEE 1364-2001 26.6.18)

NOTE
1. A Verilog HDL function shall contain an object with the same name, size, and type as the function.
2. \texttt{vpiInterfaceTask/vpiInterfaceFunction} shall be true if task/function is declared inside an interface or a modport of an interface.
3. For function where return type is a user-defined type, \texttt{vpi_handle} (\texttt{vpiReturn},Function_handle) shall return the implicit variable handle representing the return of the function from which the user can get the details of that user-defined type.
4. \texttt{vpiReturn} will always return a var object, even for simple returns.
30.24 Alias Statement

Examples

alias a=b=c=d

Results in 3 aliases:

    alias a=d
    alias b=d
    alias c=d

    d is Rhs for all.
30.25 Frames (supercedes IEEE 1364-2001 26.6.20)

NOTES
1. The following callbacks shall be supported on frames:
   - cbStartOfFrame: triggers whenever any frame gets executed.
   - cbEndOfFrame: triggers when a particular thread is deleted after all storage is deleted.

Comment to editors: Please note that we have changed the vpiParent handle from the LRM. vpiOrigin now gives the originating scope or task/function call. Note also that this diagram is incompatible with the one in IEEE 1364, but the IEEE is currently also making incompatible changes to that diagram.
30.26 Threads

NOTES

The following callbacks shall be supported on threads

— **cbStartOfThread**: triggers whenever any thread is created
— **cbEndOfThread**: triggers when a particular thread gets deleted after storage is deleted.
— **cbEnterThread**: triggers whenever a particular thread resumes execution
30.27 tf call (supercedes IEEE 1364-2001 26.6.19)

NOTE:
1. the vpiWith relation is only available for randomize methods (see section 12.6) and for array locator methods (see section 4.15.1).
2. For methods (method func call, method task call), the vpiPrefix relation will return the object to which the method is being applied. For example, for the class method invocation packet.send();
   the prefix for the "send" method is the class var "packet"
mod path properties:
- delay
  - vpi_get_delays()
  - vpi_put_delays()
- path type
  - int: vpiPathType
- polarity
  - int: vpiPolarity
  - int: vpiDataPolarity
- hasIfNone

NOTE:
1. specify blocks can occur in both modules and interfaces. For backwards compatibility the vpiModule relation has been preserved; however this relation will return NULL for specify blocks in interfaces. For new code it is recommended that the vpiInstance relation be used instead.
30.29 Concurrent Assertions

Clocking event is always the actual clocking event on which the assertion is being evaluated, regardless of whether this is explicit or implicit (inferred)
30.30 Property Decl

- property inst
- property decl
- property spec

(name
  str: vpiName
  str: vpiFullName
  definition location
  str: vpiDefFile
  int: vpiDefLineNo)
30.31 Property Specification

NOTE
Variables are declarations of property variables. You cannot get the value of these variables.

NOTES:
1. within the context of a property expr, \textbf{vpIOpType} can be any one of vpiNotOp, vpiImplyOp, vpiDelayedImplyOp, vpiAndOp, vpiOrOp, vpiIfOp, vpiIfElseOp
   Operands to these operations will be provided in the same order as shown in the BNF.
30.32 Multiclock Sequence Expression

multiclock sequence expr ➔ clocked seq

clocked seq ➔ (sequence expr) ➔ (expr)

vpiClockingEvent

vpiDisableCondition ➔ (expr)

property inst ➔ arguments ➔ property decl

definition location
int: vpiDefLineNo
str: vpiDefFile
30.33 Sequence Declaration

NOTE:

the vpiArgument iterator shall return the sequence instance arguments in the order that the formals for the sequence are declared, so that the correspondence between each argument and its respective formal can be made. If a formal has a default value, that value will appear as the argument should the instantiation not provide a value for that argument.
30.34 Sequence Expression

Notes:
2. Within a sequence expression, \texttt{vpiOpType} can be any one of \texttt{vpiAndOp}, \texttt{vpiIntersectOp}, \texttt{vpiOr}, \texttt{vpiFirstMatchOp}, \texttt{vpiThroughoutOp}, \texttt{vpiWithinOp}, \texttt{vpiUnaryCycleDelayOp}, \texttt{vpiCycleDelayOp}, \texttt{vpiRepeatOp}, \texttt{vpiConsecutiveRepeatOp} or \texttt{vpiGotoRepeatOp}.
3. For operations, the operands are provided in the same order as the operands appear in BNF, with the following exceptions:
   \texttt{vpiUnaryCycleDelayOp}: arguments will be: sequence, left range, right range. Right range will only be given if different than left range.
   \texttt{vpiCycleDelayOp}: argument will be: lhs sequence, rhs sequence, left range, right range. Right range will only be provided if different than left range.
   all the repeat operators: the first argument will be the sequence being repeated, the next argument will be the left repeat bound, followed by the right repeat bound. The right repeat bound will only be provided if different than left repeat bound.
30.35 Attribute (supercedes IEEE 1364-2001 26.6.42)

30.38 waits, disables, expect, foreach (supersedes IEEE 1364 26.6.38)
30.39 Expressions (supersedes IEEE 1364-2001 26.6.26)

NOTES:

1) For an operator whose type is `vpiMultiConcat`, the first operand shall be the multiplier expression. The remaining operands shall be the expressions within the concatenation.

2) The property `vpiDecompile` will return a string with a functionally equivalent expression to the original expression within the HDL. Parenthesis shall be added only to preserve precedence. Each operand and operator shall be separated by a single space character. No additional white space shall be added due to parenthesis.

3) new `vpiOpTypes`: `vpiInsideOp`, `vpiMatchOp`, `vpiCastOp`, `vpiPreIncOp`, `vpiPostIncOp`, `vpiPreDecOp`, `vpiPostDecOp`, `vpiIfOp`, `vpiCycleDelayOp`. The cast operation is represented as a unary operation, with its sole argument being the expression being cast, and the typespec of the cast expression being the type to which the argument is being cast.

4) new `vpiConstType`: `vpiNullConst`, `vpiOneStepConst`, `vpiUnboundedConst`. The constant `vpiUnboundedConst` represents the $ value used in assertion ranges.

5) the one to one relation to typespec must always be available for `vpiCastOp` operations and for simple expressions. For other expressions it is implementation dependent whether there is any associated typespec.

6) Variable slices are represented by part-selects whose parent simple expression is an array variable.
30.40 Event control (supersedes IEEE 1364-2001 26.6.30)

```
30.40 Event control 'at'
```

NOTE—For event control associated with assignment, the statement shall always be NULL.

30.41 Event stmt (supersedes IEEE 1364-2001 26.6.27)

```
30.41 Event stmt
```

30.42 Process (supersedes IEEE 1364-2001 26.6.27)

```
30.42 Process
```

NOTE—vpiAlwaysType can be one of: vpiAlwaysComb, vpiAlwaysFF, vpiAlwaysLatch
NOTE: vpiOpType will return vpiAssignmentOp for normal non-blocking '=' assignments, and the operator combined with the assignment for the operators described in section 7.3.

For example, the assignment

```
a[i] += 2;
```

will return vpiAddOp for the vpiOpType property.
